Certainly good at HF and UHF when the skin depth is likely to be a small
fraction of the conductor radius.

> Apparently, something additional happens for high-loss lines.

Not so much high loss, as low frequency. Both L and R are frequency
dependent assuming normal (non superconducting) metallic conductors. G
and C may have a frequency dependency depending on the dielectric
characteristics.

Once the frequency is high enough so that the current can be considered
to flow only on the skin of the conductor, the effective AC resistance
is proportional to the square root of the frequency and the inductance
is constant. At frequencies below the above defined 'critical
frequency', the internal inductance must be considered as well as the
complicated frequency dependence of resistance.

Chipman

Yep.

At the

> the impedance of the load apparently somehow interacts with the
> characteristic impedance of the high-loss transmission line to upset
> the ideal relationships in your equation above.

The relationship is correct for all frequencies and standing wave ratios
as long as the correct frequency dependent values of transmission line
parameters are used. The wave equation still describes the relationship
between current and voltage. The additional 'interference' terms appear
when calculating the energy distribution and loss characteristics.

I goofed on the part that is talking about transducer loss. I should
NOT have included the "Transducer Losses" in my statement above. The
Transducer losses do, as you say, include the normal attenuation of
the line, which is indeed a dissipative loss.

I'm not sure what you are saying about the loss nomograph on the Smith Chart. If that's wrong too, then we're in big trouble. Everything ever written that I have seen about the Smith Charts agrees that the actual losses in the transmission line are indicated by the collapsing of the circle as one traverses the transmission line. All you have to do is read the "loss in 1 dB steps" scale to determine those losses.

No possible way that could be accomodated with any degree of safety or convenience at all Bill.

On a sailboat, the conventional way to run a long piece of wire is up the mast at the stern. Either a wire or an insultated backstay is used. The backstay is the guy wire at the back of the boat holding the mast up. Insulators can be cut into the backstay allowing it to be used as an antenna. I don't care for that much as it seems possible for the backstay insulators to fail (even though the manufacturers claim otherwise), leading to a dismasting. People die that way. So I run a simple copper wire up the back between the 2 backstays.

At the stern of most sailboats, there are exterior storage lockers. A very heavy stainless steel "chain plate" is attached to the hull at the stern, and the back stay (or in my case stays, as I have two) are attached to those chain plates. My chain plates are right on the transom which is typical of most sailboats. That's RIGHT at the back of the boat. There is a stern locker nearby for storage of stuff you want to use in the cockpit. That is a typical layout for most sailboats. Then, heading forward there is a cockpit area, then the companionway down into

the cabin. Below the cockpit is engine, and no living space. The livingspace typically begins at the companionway.

Typically, the radio is located at the nav station, which is midship in the cabin, in my case about 15 feet from the stern locker where the tuner is located. My boat is quite typical of most sailboats. There is no living space in the vicinity of the transom nor is there living space under the cockpit. Some sailboats feature a center cockpit, in which case a large master stateroom is usually under the back of the boat. That's not where a radio belongs either. It belongs at the nav station.

In other words, in order to use pigtails "right under the antenna" as you suggest I would have to go outside of the cabin by climbing up the companionway, walk to the very back of the boat (a place you do not want to be when in heavy weather), open a stern locker, get down on my hands and knees and fiddle with the pigtails whilst pitching about as if in a washing machine of the spin cycle. Then go (stagger really) back inside to use the radio. Switch bands? Do the whole thing again. By the way in heavy weather, leaving the cabin also entails strapping on a heavy safety harness, possibly foul weather wear, and then attaching the safety harness to a line that is attached to the boat, before exiting the cabin. As you can surely appreciate, pigtails or any other mechanical connections to be messed with would simply not work in the environmnent.

Simply put, the only practical solution on a sailboat is a tuner. That is why I have never yet (in over 25 years of serious messing with boats and countless sea miles under my keel) seen a ham or marine SSB equipped boat without a tuner.

It is the ONLY practical solution.

Hi Wes,

The math is on the bottom of pg. 203 which is supporting Fig. 9-26.

There is also a section entitled 8.8 Multiple reflections on ppg
174...176.

Then there is the specific math of fully specified matches at both
ends, that is at the source and the load, found in Fig. 10-7 that is
supported by discussion on ppg. 225...227.

All of this bears on discussion around and about the necessary
treatment of the Z of the Source, but I haven't supplied all the
citations within this one reference by any means.

Thanx, Wes. You needn't do all these scans. The group needs to do
their own heavy lifting to escape their naivety about source Z.

There should be no problem at all with some of the antenna being below deck. It would be good to keep it away from metal stuff of course. Longer horizontal runs tend to raise issues, though. Probably a greater chance of coupling rf into the boat's other electrical systems, and a long run of 20 feet or so (say from the backstay to a nav station amidships) can radically alter the radiation pattern. Maybe for the good, maybe not. And that is the main reason that manual tuners are questionable choices for use with backstay antennas. Nobody wants to try to manually tune a backstay antenna located at the stern if the rig is 15=20 feet away.

To avoid this run, some of us have resorted to loading the shrouds (and the whole rig as well) with an L-network quite successfully. I believe a separate wire run up a flag halyard would be an easier antenna to tune, but it would introduce other issues.

As Gary has said, it is difficult (but only mildly so) to get a resonant quarter-wave in a backstay. It would probably require an antenna impedance analyzer to find resonance. Make it a bit short and add a few turns of wire (cheap and reliable) to bring it to resonance.

Hi Bob,

Chipman devotes an entire chapter on the Smith Chart, covering each scale completely (I wonder why Reg thinks it would take so many months to accumulate this information if he, as he alludes, is already aware of Chipman's work.).

However, the nomograph discusses nothing in terms of any particular line's dissipative loss as that is outside of purpose of the chart. I'm afraid you are back in the mythical mismatch loss there. When Wes puts that particular page online, then perhaps you may find a way to fully describe your situation - including loss specific to your tests.

Chipman states quite bluntly:
"IF the transmission line of Fig. 9-26 is lossless...."

The point of my posts is that few actually read this material to appreciate the very carefully stated premises. The problems arise when derivative work is used as a source wherein that author presumes that the reader is educated in the particulars that go left unsaid.... like all Sources' Z MUST match the line for any analysis to be valid. Instead we get these trivializations of the matter that this is only a concern inhabiting only specialty sources in specialty labs.

However, as applied to your recent work, the degree of mismatch offered by your source is low enough to be negligible; but as you are not aware of its degree, then neither are you aware of the scope of your error.

When I said "you don't usually know where ground is" I meant that on a
boat what may look like real ground may not be. Usually there are a
lot of different things tied together to try and get a decent ground
for the radio. The length of those leads are a factor. There is no way
to know for sure how long the actual ground lead is without measuring
where your antenna resonates.

Cut and try with a backstay is not practical.

# 2823. Re: Additional Line Losses Due to SWR

Newsgroup: rec.radio.amateur.antenna
Date: 2004-11-29 04:09:50 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <coe7ee$rf1$1@hercules.btinternet.com>
Source record: 86120

Just a few meandering thoughts -

For anyone assembling a collection of exact transmission line formulae, of which there are dozens, some more applicable to practical problems than others, it is best to begin with the most commonly used and the most complicated formulae. Don't incorporate approximate formulae or you will later wish that you hadn't.

Clear your minds of superfluous Smith Charts, standing waves, reflected power, virtual short circuits, conjugate matches, etc. A clear understanding of how transmission lines work is essential. You should be familiar with complex hyperbolic functions. Only metric line dimensions should be used.

What are required are calculating procedures which accepts all possible input data and finish with preferably a single number. In some cases, if not needed, input data can be set to zero but the facility must exist.

You will then have designed a set of step-by-step routines as in computer programs but which can be tediously and logically worked through with a pocket calculator. The number of intermediate variables can be large. But there can be only one unambiguous straight-line path through subroutines.

For example, in a large number of cases the single output quantity is related to line loss, such as insertion loss in dB, or load power in watts, or transmission efficiency in percent, or percent of input power lost in the line itself.

But before this can be calculated it is essential to calculate input impedance Rin+jXin for given attenuation in dB or nepers, given phase shift in radians and given terminating impedance Rt+jXt. Then include generator impedance Rg+jXg and internal generator volts. Having done this you are half-way through.

Some intermediate results may be useful. Such as input impedance which terminates a tuner or provides a source for a receiver.

Such intermediate results as reflection coefficient magnitudes and angles may be explicitly available but may be of no practical use. What can you do with them? The calculation is already complete. You might find an SWR somewhere in there if you recognise it but who cares.

Well, you get the idea. But if you had the source codings of some of my programs I can assure you they would not be of the slightest use. You may just as well start at the begining. There are many ways of accomplishing the same task. A mathematical program is a work of art as much as it is a set of logical rules. But only the programmer can fully appreciate the beauty.

First prepare a list of proposed interrelated calculating formulae or
routines.
Then write the routines on paper.
Then test them on a computer.
Then spend the next 12 months removing the bugs.
Ditto, removing the bugs caused by the debugging operations.
Then publish them in the ARRL Handbook, 2009 edition, using a better
printer.
---
Reg.

Here's the equation that Ramo and Whinnery says is an approximation
for low-loss lines.

Z0 = SQRT(L/C)[1 + j(G/2wC - R/2wL)]

If G = C * R / L then Z0 = SQRT(L/C)

So why did Ramo and Whinnery say it is an approximation for low-loss
lines?

I notice nobody has mentioned traps. That would be another way. 50 feet is long enough to have it work 75 meters, if there are several traps in line. From what I understand, the antenna is mostly vertical. Tuner or not, a 50 foot vertical is getting to be too long for low angle radiation at the higher bands.

My response was to your earlier post:

+Reg Edwards wrote:

+> It was obvious I introduced G = C * R / L simply to show that a
+line's Zo
+> can be purely resistive even when it is NOT lossless. It can have
+any loss
+> you like.

To which you responded:

+Ramo and Whinnery are the authors of my 50's college textbook on fields
+and waves. Of course it could be a misprint, but they say your above
+formula is an approximation that is good for low-loss lines.

+Apparently, something additional happens for high-loss lines. Chipman
+seems to agree with Ramo and Whinnery when he introduces some +additional
+interference terms (discussed some time ago on this newsgroup). At the
+time, I didn't realize the additional terms were interference terms but
+the impedance of the load apparently somehow interacts with the
+characteristic impedance of the high-loss transmission line to upset
+the ideal relationships in your equation above.

As Reg points out, if G = C * R / L then Zo is purely resistive for any
frequency for which the relationship holds. This is the well known
'distortionless' condition.

The formula just introduced to the thread

Z0 = SQRT(L/C)[1 + j(G/2wC - R/2wL)]

is an approximation of the well known exact formula:

Z0 = sqrt( (R + jwL) / (G + jwC)) which can be found in any treatise on
transmission lines.

The equation just introduced from Ramo & Whinnery consists of the first two terms of a particular series expansion of the exact formula for Zo, and is therefore an approximation to Zo.

Reg's exact formula for the distortionless condition can be easily derived by noting Zo is purely real when arctan(wL/R) = arctan(wC/G) and working through the algebra.

Setting the imaginary part of Zo to zero in the approximate formula for Zo will in general result in an approximation of the conditions required for the distortionless case (Zo purely real). In this particular case it turns out that the conditions derived from the approximation to Zo are in fact exact. A fact which can be easily verified by direct algebraic manipulation of the exact formula for Zo. Use of an approximation developed for a specific purpose to draw conclusions outside the validity of the approximation will likely lead to incorrect conclusions and provide very little insight into the system being analyzed.

I may be obsessing.

When putting trifilar winds around a toroid, does it matter how the three wires are twisted before they are wound?

The easiest way is to just twist the two "outside" wires around the "center" wire. The outside wires would wind up a little longer. It would just a moment longer to plait or braid them, which would make them equal length. Does it matter?

Yes it does matter, if you are trying to hold a particular Zo to
get maximum bandwidth. I use ribbon cable or multiwire
rotator cable to get the spacing between the wires to be
consistent. The bandwidth is MUCH wider than you
get with twisting or braiding.

Rhombics are "big" in the physical sense, but you can the same gain in much
less
space with a Yagi, plus much less sidelobe power. Also, I'm not sure what
you
mean by "low bands". On 160 and 80 meters, you either need verticals or a
lot
of height. A 160 meter rhombic would require 20 to 40 acres of land.

Now are you still sure you want to build rhombics?

Hi Nana

I won't be much help, but have seen what you are looking for at one of these two truck stops. Don't remember which one for sure so I'll name both of them.
It was either the BP at 1897 Genesis Road, Crossville, TN or the BP at 121-A Luyben Hills, Kingstonsprings, TN
I had stopped both places for fuel last week and one of those had the antenna topper your looking for.
So at least you know they are still in production and for sale somewhere.
Sorry, I don't remember the distributors name on the display cards they were packaged in.
Brockman Custom Parts had some a few years ago, but that's no help is it.

Instead of searching for Trucker Babe, try Naked Lady it might bring up more results.

Hi Wes,

Thanx very much. I can see one of two results from this general
availability. The readership here can:
1. Avoid it in stunned shame (the embarrassment in coming of age);
2. Accept it as a remarkable revelation (because it's on the web).

I would hope for a third response from those who could argue what
follows from these first principles, but the lazier ones would
complain of my "attitude" and hobble back to their beauty contests on
their crutches. ;-)

To quote one of my favorite authors, Raymond Chandler, when in "The
Big Sleep" Doghouse Reilly is admonished about the same defect, he
avers "I don't mind if you don't like my manners. They're pretty bad.
I grieve over them during the long winter evenings."

>Does it matter?

Hi Ken,

The technique matters at the peripheries of what you seek to accomplish. The tight conjunction of wires (the are properly transmission line) reduces their characteristic Z. This is a positive attribute if you seek that characteristic. Recall that the best line Z is found through the math of finding the root of the product of the two Zs being transformed (in other words, does that tight conjunction lend itself to this root of the product).

However, there are many topologies in winding these items, and not all conform to this technique. For some, you want separation so that the loss and isolation characteristics are maximized at the margins of frequency operation (typically high end use).

So, yes it matters. The real question is: Does it matter for you?

> and is therefore an approximation to Zo.

Thanks, Bart, that answers my question. I jumped to the conclusion that
since [(G/2wC - R/2wL) = 0] satisfied Reg's equation, it followed that it
must be part of the approximation mentioned by Ramo and Whinnery. I just
didn't read far enough: "For many important problems, losses are finite
but relatively small. If R/wL << 1 and G/wC << 1, the following approximations
are obtained by retaining up to second-order terms in the binomial expansions ...
it is often sufficient to retain only first-order correction terms ..."
which is what the above equation does.

From my experiences with winding small torroids for CATV, the bandwidth (at least at the HF end) definitely better when you interwind (interleave) the windings.

We put this down to the fact that it probably minimises the capacitance between the turns of the same wire. For example, suppose you use red, green and blue wires. As you progress around the circumference, you have a regular sequence of red, green, blue - red, green, blue etc etc. You will never have a red adjacent to a red etc.

Note that, in principle, you could wind bifilar and trifilar using bare wire, and (with care) never have the adjacent turns touching.

One manufacturer used to use special bifilar and trifilar wire (like miniature flat twin (and triple).

If you do want to twist, we found that twisting the wires would give you a more consistent (and lower) characteristic impedance. This is probably because, if the wires are kept in good contact with each other, the capacity per length is consistent. However, there is no point in twisting any more than is sufficient to keep the surfaces of the wires in intimate contact.

I never thought of braiding (also called 'platting' in the UK). Sound like hard work to me!

# 2845. Re: Additional Line Losses Due to SWR

Newsgroup: rec.radio.amateur.antenna
Date: 2004-11-29 20:57:16 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10qn39hsirk9s23@corp.supernews.com>
Source record: 86041

I offer a third third response.

On p. 175, Chipman states:

"Equation (8.27) demonstrates explicitly that the shape of a standing wave pattern representing |V(d)| as a function of d on a transmission line is in no way affected by the quantities Vs, Zs and [rho]s at the source."

And equation 8.29 on p. 176, the calculation of reflection coefficient, contains no source-dependent terms. I'm sure that somewhere in the book, the author derives SWR in terms of reflection coefficient.

These are the facts:

1. The SWR, positions of the standing waves, reflection coefficient seen looking into the line, impedance seen looking into the line, and dB line loss are independent of source impedance.
2. The actual amount of power delivered to a line for a given Thevenin source voltage will, of course, depend on the source impedance, just as it would if the source were directly connected to a load. Therefore, the absolute amount of power dissipated in the load depends on source impedance. The dB line loss, however, doesn't. Also, the length of time the line requires to reach equilibrium after initially turning on the source depends on the source impedance.

These can be found, explicitly stated and/or in easily interpreted equation form, in a host of references.

I see nothing in the text Wes has kindly posted which contradicts these facts, and I'm sure there's nothing elsewhere in the text that does.

I often have a hard time understanding Richard's postings, so it's possible that he's not disagreeing with the statements I've made, either. If so, I apologize for the misinterpretation.

None of us are perfect. All of us (except Jim Kelley :-) will admit to being human, i.e. capable of making a mistake. The Z(s) of the source, no doubt, has an effect on the power sourced by the source. But the "power sourced by the source" has no effect on SWR, which is independent of source impedance. Given a steady-state forward power, nothing else depends upon source impedance. If a one ohm source is capable of supplying the same voltage as a one megohm source, the steady-state results will be identical.

Given any source with any source impedance, there exists a forward power. Given any forward power, the source impedance during steady-state is completely irrelevant.

Hi Roy,

No doubt. As I am not immediately interested in the reductionist art
of SWR, then the remainder seemed of little relevance to line losses
and the contribution of source Z to power determination error.

You continue, in part quote of a part quote:
>representing |V(d)| as a function of d
which given you offer no more comment upon it, gives me the impression
you are unaware of what function d is. The point of the matter is that
this very equation you chose is examined in isolation, by you, but is
returned to on several occasions by Chipman where he quite
"explicitly" exhibits how V(d) ranges wildly for situations where both
ends of the line are terminated by forced mismatches. This is a
uncommon technique for determining SWR (still not my point, but
nonetheless an obvious example).

And yes, I realize
>I often have a hard time understanding Richard's postings
and I often grieve over this on long winter evenings. Roy, you are
too coy by half. ;-)

However, your aside into SWR shape and the focus on reductions to
typical applications (source matches line) does leave a dilemma
because there is now conflict between your isolated quote of Chipman
and the demonstration of EZNEC as reported by my late, short lived
thread. I would offer that EZNEC fully supports Chipman's other
comments on this same quoted material you drew from him, and goes to
the matter I offered of an uncommon technique for SWR determination.
My EZNEC reports are also supported by bench results, and other
sources also recited here. All this seems to leave you on the outside
looking in. As it broaches upon topics that you have long cautioned
me that discussion would not "change your mind," I doubt this will go
any further.

wrote:
>Once again, it's not clear to me just what you're trying to prove.

Hi Roy,

Troubles me too....

In the interim I have recognized where I went off the deep end in the thread I have alluded to. The attempt there was to reproduce, in EZNEC, results obtained at the bench and offered through various references which demonstrate Mismatch Uncertainty. Although the model of the transmission line was certainly of the highest quality, EZNEC lacks the capacity to separate forward and reverse waves for analysis. In that regard I mistakenly attributed the results I obtained to my bench results.

Situation is that with a SWR meter moving along a line mismatched at both ends, there is a distinct variation in the computed Power. When I did this at the bench, I could evidence about a 30% variation which was consistent with theory and clearly exhibits the contribution of Source Z when it is other than 50 Ohms. When I recently attempted to model this in EZNEC, I again saw the wild fluctuation of power that seduced me with its complementary results into thinking I had achieved the same results. When I revisited those results (EZNEC ones that is), all I had done was prove the mismatch through the abstraction of the power reported at my moving test load. When I reverse engineered the voltages from the known R, it became obvious that the VSWR corresponded to every expectation - or was close enough given the degree of resolution I had available with 20 test points distributed along the line. Chipman describes this in his late chapters - one of which Wes has provided.

However, this does nothing to detract from Chipman's work that includes the FULL treatment of all variables that lead to the common usages. Such treatments include the Source with full characterizations and goes on to discuss the R of the Source and not just its Z. That so many texts disregard this level of examination does not deny its importance to issues that go beyond SWR. Those lesser texts presume Source Z unlike Chipman, and its significance is lost to the student who hasn't been grounded in the fundamentals. And thus we arrive at the topic at hand and listed in the Subject Line: Additional Line Losses Due to SWR. In that regard, the Source Z is entirely an active player and any additional mismatch that it presents to the system eventually finds additional loss (caloric) injected into it. Chipman's work in that regard is complete enough to offer Bob the

framework to render a complete solution and to explain how and why this additional loss appears. It may not bear on his measurements directly (the measure of a stub's Q as it eventually turns out), but it is related closely enough to provide tangible leads.

The fact remains that a transmission line/antenna system has the
same characteristics whether one watt, 100 watts, or 1000 watts
are input to it, i.e. the efficiency and SWR of the antenna system
does not depend upon the source impedance.

Source record: 86054

I am really new to ham radio and have a couple of questions. I bought a used
Yaesu FT-980 and now am trying to set up an antenna for it.

Option 1: AT-100 Pro / 4:1 balun / randome long wire. I am experimenting with this in my office at the moment. I cut a copper wire (about 3/16 inch strand) and attached it to the antenna line of balun. I ran another short wire to the ground of the wall receptacle. Connected balun to AT-100 Pro with 25 foot coax, then connected the antenna tuner to FT-980. I powered up the transceiver and tried a few differant frequencies. The AT-100 Pro made some grinding noise and was able to bring the SWR down to around 2, the power meter went to about 100. The antenna was drapped across some cubicles (dilbert office). After a short while the antenna wire got a bit hot to touch, and tingled a bit when I touched it. Is this normal? Should I use a longer wire?

Option 2: I am thinking of getting an MP-1 vertical antenna instead of random wire. Can I use the antenna tuner with this? Will it heat up? How do I ground it? Do the counterpose wires spread out act as a ground?

Sorry for all the questions, I am a total beginner.

Thanks for your help,

Glenn

Hi Bob

Painting won't change any of the properties unless the paint contains metals or heavy carbons.

You might consider Krylon over Rust-Oleum though.
Almost everything I have ever used Rust-Oleum on, it has taken two or more coats and then it peeled off in many spots within the first few months.
A number of years ago we painted two commercial lawn mowers, one with Krylon and the other with Rust-Oleum, both with the same prep before painting.
We had to repaint the Rust-Oleum painted mower the following year, the Krylon mower was never repainted, nor did it need it.

I would go for the Icom TS50... unless you mean Kenwood TS-50... then
I would go for that.. ;-)

The TS50 is a great radio but lacks modernday filtering/dsp.

Glenn wrote:
> I am really new to ham radio and have a couple of questions.ffice).
> After a short while the antenna wire got a bit hot to touch, and
> tingled a bit when I touched it. Is this normal?
Yes - it's not a good idea to touch an antenna when it's transmitting -
especially 100 watts.

> Option 2: I am thinking of getting an MP-1 vertical antenna instead of
> random wire. Can I use the antenna tuner with this?
Yes - although you may not need it: the MP1 has an adjustable coil that
should do the matching for you, rendering the tuner superflous.

Will it heat up?
Shouldn't if it's tuned up right.
> How do I ground it? Do the counterpose wires spread out act as a
> ground?
Yes.

Hi, Glenn -

I hope the experts will have something to say, but someone ought to
mention that you shouldn't expose your officemates to 100W of rf energy.
Can you get that random wire outside?

Those cubicle dividers have metal tops & skeletons, no? Those are no
doubt coupling to the antenna wire if it's draped over them. This just
generally messes up the situation. Another reason to get that wire outside.

The wire heating up is no doubt due to this coupling with office
furnishings. The voltage varies along the wire, and at places it can be
thousands of volts. A metal object in contact with such a spot could arc
with the antenna wire.

An antenna wire should be as high as possible and *in the
clear* (not touching any buildings, tree limbs, lamp posts, etc). That's
why an insulator is put at the end of an antenna wire, with a rope going
the rest of the way to the antenna support (tree, etc.)

The MP1 has been used and it works. Being a shortened vertical, it tends
to radiate mostly upwards on the lower bands. This can be good (40M in
the daytime to talk within a few hundred miles) or bad (40M at night
when you might want to do dx may not be so great). Can you put the MP1
outside, even temporarily? The counterpoise wires constitute the rf
"ground" in that case. They should be cut to 1/4 wave on the lowest band
you want to operate on and fanned out around the base of the antenna.

Please don't hesitate to ask more questions. Hope this helps.

Antenna boys - please chime in!

73 - Lee H, NB7F

Hi John,

I know the TS-50 (Kenwood) and it is a good, small rig. Try to get the companion power supply from Germany (sorry, don't know the product name) which is a switching power supply (equally as small, but suitable and a lot lighter than big linear supplies).

>I realise the learning will continue AFTER I get the pass certificate

The downside with this, or any other "small" rig is that you will indeed be continuing to learn. This is because there's not enough buttons and knobs to go with all the functionality and you have to learn how to navigate their software menus (not always intuitive) and cryptic displays.

There are two roads that this offers. For someone who doesn't want to fiddle with knobs and such, you can figure out the menus, set your options, and simply talk on the rig for ever after. For someone who does want to tune, tweak, and adjust - you really need something bigger; and if that means outside of your budget, it then suggests older.

Another point to consider, if you stay with this hobby long enough, you will eventually get at least two of everything. So don't approach a decision thinking you won't be facing that choice again. As such, buy something affordable that leaves you enough money from your budget to buy the other things that go with it - mike, key, speaker, antenna tuner, power meter, and certainly enough transmission line, wire, then insulators, some rope and pulleys and so on. Oddly enough, most of these secondary items will be with you longer than your rig. Older transistorized rigs that still work, will undoubtedly work for as long as you own them and pass them on.

If you want to bury your hands in the guts, try tube sets. They are bigger yet, and don't mind your first time mistakes on fixing things. Plus all the voltages are much higher, and touching the wrong lead lends a sort of zest to this past time. Cheaper than gambling and you get the thrills of javelin catching without needing to get out of your house.

Roy, W7EL wrote:
"I`m sure that somewhere in the book the author (Chipman) derives SWR in terms of reflection coefficient."

I`ve read, here I believe, that Chipman`s book is one of the "Schaum`s Outline" series. It would need to derive SWR in terms of reflection coefficient to be complete.

Attenuation of a uniform transmission line is a function of the loss per unit length and the total length. A line with SWR has higher voltage and current in spots than a matched line. Thus it has higher loss. Analysis is complicated in lossy lines due to decline in SWR back from the reflection point. If SWR at the reflection point is less than 2:1, added loss due to SWR is hardly detectable. Such a line is considered perfect.

The ARRL Antenna Book has graphs relating SWR to fopward and reflected power readings as given by a Bird wattmeter. The "Antenna Book" also has a graph of additional loss due to standing waves versus the SWR at the load for values between SWR=1.5 and SWR=20.

I don`t have a dog in this fight. There is nothing particularly strange about solutions to equations which describe particular relations on a transmission line. The functions are not erratic but continuous and predictable. Selection of the right formulas is all that`s needed to get the right answer from the right data.

Best regards, Richard Harrison, KB5WZI

Source record: 86070

Advantages
1. Reduced possibility to RFI, TVI to the neighbors
2. An ego booster if you can do the mostest with the leastest
3. A challenge of your skills
4. Fun to be the underdog (for some, others wud rather be top dog)
5. Enhances your skills as it can be more difficult to make contacts
6. You will soon find it is generally easier to make CW QRP contacts -- so enhances your CW skills
7. Equipment is usually cheaper
8. Lot easier to operate on batteries or solar power than 100 watt rig
9. A great brag tape "I worked DXCC QRP" there is an ARRL award for QRPers
10. Fun to calculate miles per watt and improve your record
11. Less chance of frazzling your brain if close to the antenna
12. The dog will probably live if it chews on the antenna
13. Less chance the XYL will complain -- "Ur gettin in the telephone"
14. A snap at the height of the solar cycle on 10 and 12M ( little tougher on the other bands)
15. At the DX club, a big gun flashes a rare QSL card (he/she runs a KW) you show your QRP card - Gotcha
16. Easier to homebrew a QRP rig
17. Meets part 97 for using the lowest power necessary to make a contact (Too many KW's on the band)
18. It is a David and Goliath thing
19. You are only down ~ 2 S-Units compared to running 100 Watts

Disadvantages
1. You can spend days trying to break a pileup of a rare station
2. For the determined and patient only (read that one again)
3. Just plain frustrating when you can hear the a station quite well and they can't hear you
4. Ya better have a real real good antenna and low loss transmission line
5. Tough to be QRP on the low bands (80 and 160M, too much noise)
6. Other Hams will tell you QRP is for sissies ( but the enlightened know better)
7. For the upper bands, at the minimum of the solar cycle -- man ya gotta work work work to get contacts
8. Read number 2 again
9. Read Number 2 again

Off the top o da head answers

Hi John

A very hard decision indeed as it depends on what you want to do with amateur radio, but need experience to make such a decision!

Have you made contact with other amateurs in your area? Like through a club? You may be able to do hands on comparison of various radios both recent and old. You will also then be able to apply this to understanding what the listed specifications mean and whether they are important or not. (Like good receiver sensitivity on 80M is pretty pointless given the amount of general band noise) If you are comparing DSP the only real good indicator is your own ears!

You could of course buy something super cheap and old, learn from it and then go to something more expensive..

Cheers Bob VK2YQA

Source record: 85979

Hi Simon

Assuming you are not just talking about the technical "challenge" of operating with low power.

Adv
- Less power consumption
- Less chance of causing TVI/BCI etc
- Transmitters of lower power tend to be cheaper than those of higher power. You can also get away with a less "clean" TX (spurious o/p etc)
- Matching networks etc dont need to be able to withstand as high voltage/power. (Also means cheaper)
- Almost zero chance of RF burns off the TX!
- Can run the setup off batteries for the camping trip away.

Dis
- Generally speaking a bigger investment in antenna height and design is needed. Think about what direction it radiates and keep ground losses to a minimum.
- Signals have more chance of being noisy so you may have to use your ears to do a lot of filtering. This generally means you will have the audio volume higher. (If you have a PC you might like to use it for DSP noise reduction)
- You may have to spend some time supressing local noise noises so you can hear the weaker (QRP) stations.
- In a "dogpile" of stronger stations people wont hear you so well.

If your license allows it you may want to try some of the narrow band keyboarding modes (eg PSK31). You can easily carry on a QSO with 20W all around the world.

Good luck!

Cheers Bob VK2YQA

What makes DSP filtering better than Xtal filters is that it is
programmable, not hardwired. The parameters of a DSP filter are
continuously variable although not usually implemented that way
in most amateur radio receivers. Given the processing power
necessary for a filter, one can theoretically have any of a
near-infinite number of filter configurations.

Reg, you could probably program a DSP audio filter that runs on
a PC and outputs audio through the sound card like the ClearSpeech
speaker systems. PSK-31 software packages for the PC certainly contain
a number of DSP filters and other DSP algorithms.

Note that Digital Signal Processing is not limited to filters.

> I don`t have a dog in this fight.

Neither do I, Richard. The ARRL Antenna Book seems to assume that the loss in a line is proportional to forward power plus reflected power. If reflected power equals zero, then the losses are matched line losses. I posted an example through Google to which nobody responded so I will re-post it here:
**********
Here's an example. Assume 100w is delivered to the load for both the matched and unmatched conditions. Assume 3dB matched line loss in the transmission line. Assume an SWR of 5.83:1 (rho=0.707) at the load for the mismatched condition.

Forward 200w------------3dB loss-------------Matched Load 100w

Forward 400w------------3dB loss-------------Mismatched Load 100w
Reflected 50w both Forward 200w
directions Reflected 100w

The ARRL equations give an additional loss of 5.44dB.
**********
It is obvious (to me) that if there are reflections at the load, then more power must be sourced in order to deliver the same amount of power to the load. But I am pretty simple-minded about obvious things. :-)

It sounds an awful lot of money for something that you can make for less than ï¿½5. I will hapilly make you one that will work just as well for ï¿½30 or if you have to buy one go for the Emtech ZM2. They are half the price and work fantastically well. I bought one direct from the States for about ï¿½60 and it is great up to 20W.

Hi Reggie,

DSP, depending on the artistry of the programmer, can do very well
with removing periodic (coherent) noises like birdies and heterodynes.
It can also reduce some incoherent noise. Some filters are adaptable
in that they can recognized (mostly coherent) noises and automatically
reduce them.

As for filtering, DSP filters are capable of skirt selectivity that is
impossible to achieve with any other means. Here too, they are user
configurable (if the option is available) to tailor the skirt slopes
and bandwidth independently and maintain a very low pass band ripple.
All of this is performed through discrete Fourier math, with the
routines in software called IIR or FIR filters. IIR is Infinite and
FIR is Finite Impulse Response.

The software routine, tied to an ADC chip, takes samples and feeding a
delay line, taps that line to feed the same signal (in proportions)
back to the input. Some of this might be compared to the Analog
BiQuad filters but this delay line I speak of actually exists entirely
in software as an algorithm (although early examples in a hybrid
design did this in hardware with greater sophistication than the
BiQuads).

The downside is the quality of the audio has that hollow pipe sound or
exhibits obvious sampling clock signal fed into the audio stream. As
with all digital design, it must be preceded by analog filters to
prevent spectrum folding (high frequency components being translated
into low frequency products) and post filters to smooth out the
product (if the software can't cope).

The sampling rate is the limiting factor. Early DSPs sampling at
least twice the highest audio frequency expected (the Nyquist limit)
established the clock rate and the processor had to perform all the
instructions between those samples. Later DSPs pushed the sampling
rate higher such that you could design filters in the IF range. This
was the second generation DSP of about 10 years ago. Of course, that
IF range was in the 10s of KHz, perhaps as high as 100KHz.
Traditional Analog IF design in this range was already perfectly
suited to razor thin filters with steep skirts, so the advantage was

in the adaptability.

Cheap, external, audio DSPs easily make up for any receiver's lack and the IF DSP is arguably worth the cost for the beginner.

Using 100 watts forward and 50 watts reflected into the "Antenna Book" graph gives an SWR of 5 or 6. If I had my Bird SWR sliderule at hand, I could be more precise without lifting a calculator.

According to the "additional line loss graph", this SWR adds about 2 dB to a matched loss of 3 dB for a total loss of about 5 dB with such a mismatch.

I'd be more comfortable with their claims of high efficiency, low
loss, and wide matching range if they actually provided some numbers.
It's true that some link-coupled tuners (e.g. a well-done Z-match)
have good matching range, but others (e.g. the Johnson Matchbox) have
a reputation for having a relatively limited matching range. The
devil's in the details.

As to losses: as I understand it, in a typical T-match tuner, most of
the losses occur in the coil, with only a small fraction of the loss
being in the capacitors. The claim of low loss in the "FlatPak"
variable caps may very well be quite true, but may also not be all
that relevant when comparing the QPak to more traditional tuners.

The "FlatPak" caps look interesting. I'd guess that they're a form of
butterfly cap, with fixed connections to one or two layers of
butterfly plates, plus and a single rotating stator. Maybe a very
narrow plate plate spacing and some form of insulating dielectric
(Teflon sheet)? This would allow for relatively high maximum
capacitance, low minimum capacitance, shallow depth, and reasonable
maximum standoff voltage. The sealing and gasketing of the caps may
very well be a necessity... you really wouldn't want to get dust or
dirt in between the plates and dielectric!

[A guy in our local ham club showed off a built-completely-from-scratch
T-match tuner last year, with disc-shaped caps built along these same
lines and a homemade roller inductor. Very atypical-looking device,
striking and quite beautiful. It beat out my own project to take
first place in the competition, and it certainly deserved the win!]

The toroidal coils in the QPak look nicely done, and I'd guess that
their power handling capacity is well beyond the 25-to-50-watt rating
of the tuner. I'd guess that the tuner's power handling capability is
limited by the maximum voltage across the caps, when working into
difficult loads. Arcing over an air-variable cap can be spectacular,
but I suspect that arcing over one of the FlatPak caps might burn the
dielectric badly enough to permanently damage it.

Source record: 85989

It's not obvious to me why the reactance of the link needs to be 50 ohms (for a 50 ohm resistive source) to be "ideal for the maximum transfer of power" in a conventional link coupled tuner, as VA2ERY says on the web page. Maximum transfer of power requires only that the input and output impedances be properly (conjugately) matched (and, of course, loss to be minimized), and that doesn't require the link reactance to be any particular value.(*) The argument for the supposedly wonderful performance of the tuner seems to revolve around solving this "problem", and it falls pretty flat if it's not a problem at all.

Can someone enlighten me as to why the link reactance needs to be 50 ohms?

(*) The capacitor and inductor voltage and current can be traded against each other by changing the L/C ratio. Depending on the particular components used, there'll be some ratio at which loss is minimum. But this depends on the components, and not some universal value. And it would have no effect I can see on the transfer of power, which requires only a conjugate match.

> half-way through.

Well Reg, I have a question about transmission line losses expressed in dB.
As you know, furnishing line losses in dB implies a power ratio. For a matched
line, transmission line losses in dB will be based on the ratio of power
not delivered to the load Vs the power being sourced. For instance, if
100 watts is being sourced and 95 watts are accepted by the load, then
5 watts of the 100 watts are line losses, or ~0.21 dB.

But to what power are the transmission losses referenced when reflected
power is allowed to be incident upon the source. For instance, assume
that at the source, we are reading 100 watts forward power and 85 watts
reflected power. That means the source is supplying a NET power of
15 watts to the system. If 10 watts of the total NET power of 15 watts
is being accepted by the load (implying 5 watts of line losses) does
that mean the power ratio for line losses is 33%, or 1.25 dB of losses?

Note from the matched line example above where 5 watts of line losses are
0.21 dB to the mismatched line example where 5 watts of line losses are
1.25 dB (for the same forward power of 100w), the same magnitude of loss
appears much higher as a dB value referenced to NET source power.

Source record: 85997

I just put up an inverted V for 30 meters.
I started out with each leg being 24'0". This
gave me a low SWR at 9.5665 mhz which
works out to 229.6 instead of the usual 234/F.

As I trimmed, I decided to keep track of how
much I trimmed and what the nnn/F number
would be. As I got closer to my goal of 10.15,
the number went down, eventually ending up
at 227.28/10.1955=22.292' Also, the 2:1 swr
bandwidth went up - it started at 567 kc and
ended up at 655 kc.

Either way, I got the antenna up and it's working
fine - I'm just curious why the formula for length
and the bandwidth changed as the antenna got
shorter.

Hi Ken,

The normal 5% shortening (234/F) is due to what is called "end
effect." Your ends are closer together than for the standard dipole,
and get closer yet when the V is shortened - I suppose.

Uhhhhhhh Richard, a power ratio *IS* dimensionless. Any ratio of like
quantities is dimensionless. dB is proportional to the log of the ratio
of two quantities. That ratio, e.g. of two powers, is dimensionless.

>>Note from the matched line example above where 5 watts of line losses are

I certainly didn't intend to do that. The dissipative loss in each
of the examples was 5 watts. The NET source power was 100 watts in
the matched case and 15 watts in the mismatched case.

Nope, I used leftovers from the two 150' rolls I
bought to make my 160m antenna. It's your
standard issue 14/7 stranded bare copper.

The inverted vee is about 3 - 5% shorter than a dipole at the same
frequency.
Check the Antenna books or do a Google

Adding an adapter to a Transmission Line will have no effect, except to
add insertion loss of the adapter. Adding an adapter to the antenna
itself MAY cause the antenna charactoristics to change. Most SMA and BNC
connecters are used in Transmission Lines, and not antennas themselves.
The OP doesn't really explain where the adapter is to be used. Most
small handheld devices with external antenna connections have those
connection in the Transmission Line and not in the antenna itself.

dB was not mentioned at all in Bart's posting so your comment
appears to be just an ad hominem shot in the dark. My news-
server indicates that Bart has not posted to this thread.

Let me ask my question again.

Given the dB equation for power, 10*log(P1/P2), when we say
the transmission line losses are 1 dB, what is P2 in the
denominator if it is not NET source power? There has to be
a standard. I just am not sure what that standard is. My
question is: What is the standard if not NET source power?

The magnitude of power available for being lost in transmission
line losses certainly cannot exceed the forward power minus the
reflected power, i.e. cannot exceed the NET source power. It seems
to follow that P2 in the equation must necessarily be NET power so
that transmission line losses are a percentage of the total power
available to be lost in transmission line. What am I missing?

In the previous examples, the 5 watt loss in the matched case was
5% of the NET source power of 100w. In the mismatched case, the 5
watt loss was 33% of the NET source power of 15w. It seems to follow
that the line loss in the matched case is about 0.2 dB of the 100w
of power available to be lost while the line loss in the mismatched
case is about 1.2 dB of the 15w of power available to be lost.

I'm still trying to explain the difference between Bob's dB loss
and the ARRL's dB loss. So an obvious question arose: Are they
using the same P2 in the denominator of the dB equation?

I've had a Kenwood TS-50 for years. It's a basic, very rugged and reliable good performer. Other HF xcvrs come and go here but my TS-50 is a keeper. I've used it for both fixed station and pack 'n go operations and have never had a problem with it. Which is more than I can say about some other much more expensive xcvrs I've used.

I don't have any hands-on experience specifically with an IC-703 but I have used other Icom compact xcvrs. I'm completely underwhelmed by their strong-signal handling capability. While the TS-50 is not a "competition grade" xcvr it's receiver front-end is much better than the any of front ends of compacted Icom xcvrs I've used so far. As a CW dxer front end performance matters particularly in the pileups so I'm rather fussy about how much overload and intermod I'll put up with. The TS-50 is acceptable here on this basis but the baby Icoms are not.

The 703 is a nice package which includes an autotuner, a memory keyer and here in the U.S. it can operate on six meters. It's also considerably more complex than the TS-50. For those who are big into fiddling with bells and whistles. The TS-50 on the other hand is a bare-bones basic HF xcvr without a tuner, keyer or 6M.

In your case as a soon-to-become 10 watt Foundation licensee you might look ahead to the day when you upgrade and will be allowed to use much higher powers. With a 703 you'll still be stuck with ten watts out. With a TS-50 you'd be able change one menu setting and go from 10W to 100+W out on the spot.

Hre's a couple links to user reviews which you might find interesting.

> power is allowed to be incident upon the source.

==========

Cecil, when there are several different power levels at different places in a circuit, it is entirely up to you how you reference one to another in dB. It's just a matter of convenience with the particular problem in hand.

But things are certain to become confused and indeterminate when your imagination allows two or more different power levels at the same place at the same time. For example: the so called forward and reflected power levels.

Imagination is assisted by the existence of meters which claim to measure these imaginary forward and reflected powers. Actually they do nothing of the sort. They even purport to make measurements on non-existent transmission lines.

Reflected volts - yes!
Reflected current - yes!
Reflected power - NO!

(PS : You can't deal with reflections without involving Distance, Velocity, Place and Time.)

Now Reg, that just cannot be true. Otherwise, there would exist no
conventions. It's a simple question: When you tell me that the losses
in a transmission line with reflections are 2 dB, exactly what power
are you referencing those losses against?

> Reflected volts - yes!
> Reflected current - yes!
> Reflected power - NO!

Reflected volts and reflected current existing without any associated
joules/sec???? I've heard of waves without any trace of energy before,
Reg, but I certainly didn't expect to hear miracle metaphysics from you.

Whatever happened to V*I*cos(theta) being power? The power companies
would be surprised to learn that they are not transferring any joules/sec
to their customers. Do you think I can use your argument to get out of
paying my electric bill?

Source record: 86017

Line loss itself is a comparison of two powers, those entering and leaving the line. The line loss in watts is the power entering the line at the input end minus the power leaving the line at the output end. Line loss in dB is 10 times the base 10 logarithm of the power entering the line at the input end divided by the power leaving the line at the output end. These definitions can be and are used for any two-port device.

If you truly didn't know this, it's surely because you've befuddled yourself with your forward and reflected waves of average power to the point that you've lost complete track of the fundamentals.

Roy Lewallen, W7EL

Here's an example: The source is a signal generator equipped with a
circulator-resistor that dissipates all reflected power.

100w SGCR--------------feedline------------------mismatched load

The signal generator is sourcing 100 watts. The load is dissipating
25 watts. The circulator resistor is dissipating 50 watts. The
feedline is dissipating 25 watts. What is the feedline loss in dB?

Is that 25 watts lost from the signal generator output power of
100 watts or lost from the NET power available which is 50 watts?

Well, I think he's assuming dissipative loss in both cases. But the 5 watt numbers were assumed, and there's nothing to indicate that the same piece of transmission line would produce these losses under the described conditions. Seems likely that the line losing 33% would have to be quite a bit lossier. As for the second case, we don't know what the source power was, so it presumably could also be a matched case at lower power. The example, unfortunately, compared apples to oranges.

My take on dB attenuation figures in wire and cable table data:
dB loss = 10*log(power dissipated in the line / (power dissipated in the line + power dissipated at load))

By way of reference, according to an old Standard Wire and Cable data book of mine, the attenuation factor in dB per hundred feet is:

A=4.35*(Rsubt/Zo) + 2.78*sqrt(E)*p*F

Rsubt = .1*(1/d + 1/D)*sqrt(F) (total line resistance in ohms per 1000 ft) [*Note: there might be a misprint here. The .1 would seem to indicate a conversion to ohms per hundred feet.]

E = dielectric constant

p = power factor of the dielectric

F = frequency in MHz

d = outside dia. center conductor [no units are indicated]

D = inside dia. outer conductor [no units are indicated]

The manual also discusses attenuation as a funtion of VSWR. But they do not imply that the additional attenuation is due to anything but reflection. In other words, there is no indication that reflected 'power' causes additional dissipative losses.

And.....I think Reg makes a good point about reflected power.

What makes you think the effect should be adverse? When you consider all the different radios that a given antenna could be connected to, the change from radio to radio is going to be far greater than what a 3/8" adapter is going to do (consider its electrical length at 2m...). In fact, I would hope that most HT antennas weren't meant to be used with counterpoises, but now that I think about it, I don't really know whether or not that's the case. Anyone?

I mean... the radiation pattern of a wire cut 'to length' stuck into a BNC connector on the top of an HT is going to be very seriously distorted relative to the same wire above a near-infinite ground plane.

Cell phones often use sleeve dispole antennas to avoid the need for a counterpoise...

The same as what? The feedline loss is 25 watts. What is the feedline loss in dB? Please give me a number instead of a hard time.

A signal generator is pouring 100 watts into the line because its source is seeing 50 ohms. The circulator load resistor is dissipating 50 watts of that source power. The load is dissipating 25 watts and the feedline is dissipating 25 watts. What is the feedline loss in dB?

Is the dB loss in the feedline calculated using the signal generator output power of 100 watts or is it calculated using the 50 watts of NET power available as it would be (by definition) if the source were a ham transmitter?

Why is it so hard to get a straight answer to this simple question?

The two transmission lines are completely separate and have absolutely
nothing to do with each other. The conditions are as stated.

Just curious, Ken. Your question seems to be about resonance at
different frequencies. Yet your reported measurements were about SWR.
Are you equating minimum SWR with resonant frequency?

You really don't know?

The power into the input end of the transmission line is 50 watts.
(Surely you can subtract the circulator resistor power from the source
power to find the power entering the transmission line. Can't you?)

The power exiting the load end of the feedline is 25 watts.

Therefore the transmission line loss is 25 watts.

It does seem that you've gotten yourself confused by your bouncing waves
of average power.

Definitely. I've seen my students totally overwhelmed by the fancier
radios. If they haven't got one already, I recommend that they start with
something simple, basic, and used while they get their feet wet.

That was a given, Roy. The question is: what is the feedline
loss in dB?

What do you think about Jim's definition of the power ratio
being (feedline losses)/(feedline losses + load power)?

That's *NET* power. The power into the transmission line is the 100w of
measured source power. The power dissipated in the circulator resistor is
the measured power out of the transmission line reflected from the mismatched
load. If you say to calculate the dB loss in the feedline based on the NET
power, that's what I will do.

I am trying to understand the difference in Bob's results and the
results using the ARRL equations. The magnitude of NET power to which
the feedline losses are ratio'ed may be the key to understanding that
difference.

> The power exiting the load end of the feedline is 25 watts.

That was given.

> Therefore the transmission line loss is 25 watts.

That was given but didn't answer the question about dB.

> It does seem that you've gotten yourself confused by your bouncing waves
> of average power.

Nope, you seem to be confused about what the question was. You keep
answering with what was given in the original example. The question
is: What is the *dB* loss in the feedline? Using NET power input, the
dB loss in the feedline is 3 dB, i.e. half of (100w-50w) = 50 watts.
I'm satisfied with that definition but an wondering why nobody else
has said the feedline losses equal 3 dB. What was so difficult about
that?

Incidentally, that figure agrees with Jim's equation which doesn't
even mention source power.

No. I've been down that road before - an antenna can pose a
200 ohm impedence at resonant frequency resulting in a SWR
of 4:1. I'm simply trying to get the lowest SWR in the middle of
the target range.

Hi Ken,

If you use a mono plug, just push it in part way - to the first "click".
If it's a good Switchcraft jack, the tip of your plug should engage the
'ring' contact just fine.

50 watts is entering the line, and 25 watts is exiting. The line loss is 3 dB. Surely you're able to make this calculation yourself.

I don't feel a need for a definition of a "power ratio". What you've defined is indeed the ratio of two powers, but it escapes me of what use it is except perhaps to cause confusion.

Only you could take such a simple concept as power loss in a two port device and muddle it with bouncing waves of average power.

I didn't explicitly give the loss in dB because I thought that you would be able to do it yourself. You seem to be able to, but for some reason regard it as some kind of major operation. I don't know how you do it, but here's how I do.

From my previous posting, the power into the line is 50 watts and the power out is 25 watts.

To find the loss in dB, take the ratio of input to output power, that is, 50 divided by 25, to get 2. Now take the base ten logarithm of that. (The Log key on a calculator is what I use for this complex operation. I get about 0.301. Finally, multiply that by 10, to get 3.01 dB. 3 is close enough for most of us.

I'll second that. My TS50 is ten years old this year. For several years (94 thru 99) it was permanently mounted /m (actually bolted with large bolts to deter theft) to the top of my dashboard, usually sitting directly in the Arizona desert sun. Never had a problem. These days it sits pretty much unused as a backup rig, but still works just fine. My only complaint with that rig was that the sidetone level could only be adjusted internally. Fortunately it wasn't too hard to add that knob...

I think the source of part of the confusion here is that some people apparently interpret the 'forward power' reading on their meter to mean the power into their transmission line.

The confusion I think stems from the contention that any 'reflected power' (unfortunate nomenclature IMO) is first sourced and then after reflection returned back into the source, or to a circulator load as the case may be. The latter case is certainly correct. The former is phenomenologically problematic.

Hi Jim,

By that same logic it follows that the power "into" the transmission
line was in fact never "into" the line at all but into the circulator
input, and any power finding its way into the circulator load also
never found its way into the line, but was merely reflected at the
circulator/line interface.

Hence, the power loss of the line (in dB) is
the Same.

Hence any discussion of line loss and circulators, by omitting the
circulator, is a flawed argument of line loss.

The concepts of "forward" and "reflected" power are sometimes (but not often) useful, but have to be carefully confined to a very specific set of conditions and applications. When you start thinking of them as real packets of power bouncing around inside and outside a cable, you can easily be led into a number of traps which you can get out of only by distorting reality and ultimately reaching conclusions which are more and more wrong.

I strongly suggest forgetting completely about "forward" and "reverse" power. If you must deal with directional waves, look at forward and reverse voltage and current waves. Superimpose them as necessary, and when you're done, calculate power from the result. Trying to separate moving packets of average power will eventually force you into reaching wrong conclusions, or at least to serious confusion.

The whole issue of power loss is extremely simple, and it provides a good example of how trying to invent these moving packets of average power can lead to unnecessary complication and confusion.

The "starting point" in question was a low 40m dipole, strung in the back alley of the old ARRL HQ building.

For any other antenna, anywhere else in the universe, the "magic number 234" is going to be slightly different.

The difference in SWR bandwidth between 2:1 points is a bit more complicated, and probably can't be explained in a one-liner. It will be mostly determined by the interplay between two factors:
1. What the resonant impedance is (in relation to 50 ohms), which determines the minimum SWR.
2. How quickly the reactive part of the feedpoint impedance changes with frequency, for different dipole lengths.

Source record: 85950

You've gotten a number of good answers, but maybe I can still add a little helpful information.

The resonant length and the bandwidth of an antenna are determined by some basic electromagnetic principles. Although simple in concept, the exact solution for the impedance (and therefore the resonant frequency and bandwidth) of even an elementary dipole is actually very complex. The most common method involves solution of a triple integral equation, which can't be done directly at all, but requires a computer to numerically approximate the result.(*) The formulas you see in handbooks are just a rough approximation that's more-or-less good over a limited range of conditions. The actual resonant frequency and bandwidth are affected by wire diameter, height above ground, and angle between the wires, as well as just the wire length. And the relationships aren't really simple at all.

So the bottom line is that the formulas work well enough to get you into the ballpark, from which you've usually got to do some trimming -- just as you did. You can't expect more than that from them.

Readily available, inexpensive or free, computer programs can do the complex calculations from fundamental electromagnetic principles with rather astounding accuracy, in a small fraction of a second for a simple antenna. The computed results can still differ from reality, though, due to differences between the model antenna and the real one, like nearby objects or wire insulation not included in the model, wire sag, capacitance of end insulators, common mode feedline current, and so forth. But they'll still get you much closer than the simple handbook formulas. However, the simple formulas and a bit of cut and try are perfectly adequate for many simple antennas, and might easily be faster in the long run for someone not familiar with the programs.

(*) Before the ready availability of computers, many different methods were devised to approximate the solution, with varying degrees of complexity and accuracy.

that tuner matches a random wire for frequencies from 1.8 megacycles
up through 30 megacycles. if that's the range you're going to be
listening in on your S-40B, it should work fine.

Ken, I guess I'm still confused.

As I understand it, one cannot reliably determine the exact resonance of a dipole by finding the point of minimum SWR. Until this measurement issue is resolved, there would seem to be little benefit to seeking an explanation of why the formula appeared not to work.

It is probably too late now, but if you had used an impedance bridge (MFJ or Autek, for example) you could have found resonance at the point of zero reactance. All within the limits of the instruments, of course.

Some of the posts suggest other reasons why the formula might not work, but it is not yet evident to me that it didn't work.

Sorry my earlier post was not more clear. (I'm even sorrier for this post if you actually used an impedance bridge! Hi.)

> 3 dB. Surely you're able to make this calculation yourself.

Surely you can appreciate the potential for one person to use the
signal generator output power as the reference for the dB loss
in the transmission line while another person may, as you do,
reference the line losses to the difference between the signal
generator output power and the power being dissipated in the
circulator load.

I suspect Bob and the ARRL are using different reference powers
in their calculations. My technician at Intel would have reported
the 25 watts of feedline loss above referenced to the signal
generator output power of 100 watts as was customary.

> I don't feel a need for a definition of a "power ratio". What you've

> it is except perhaps to cause confusion.

Huh???? A "power ratio" is the *DEFINITION* of dB as applied to power.
Talking about dB is meaningless unless the two powers are defined.

A direct quote from _Reference_Data_For_Radio_Engineers_

"By *definition*, number of dB = 10*log(P1/P2)"

The RF technician I worked with at Intel was directed by his manager to
report all powers in dB referenced to the signal generator output which,
in the above example, was 100 watts. His figure for dB loss in the transmission
line would be different from yours and you would be the one getting a bad
review for not following directions.

Like I said earlier, your refusal to define the powers being ratio'ed
may spread confusion instead of information.

The confusion comes about when the signal generator output power
is used as the reference, as is customary in a number of companies,
including the Intel cable group when I was there. Forward power is
*NOT* measured. Signal Generator Output Power is measured and all
dB measurements are referenced to that power.

> The confusion I think stems from the contention that any 'reflected

Another example of a physicist rejecting engineering principles.
I suggest you review HP's Ap Note 95-1 on S-Paramater analysis to
refresh your knowledge of the engineering definition of power.

|a1|^2 is forward power on the source side.
|b1|^2 is reflected power on the source side.
|a2|^2 is reflected power on the load side.
|b2|^2 is forward power on the load side.

Very flawed logic as can be proven by observing the modulation
associated with the circulator. That modulation has obviously
made a round trip to the load and back. Sorry about that.

==========

The resonant length of an antenna depends on -

Length of wire.

But also to a far smaller extent on -

Increasing conductor diameter.
Increasing conductor insulation thickness.
Reducing height above ground.
Close proximity to antenna supports, buildings, trees and indoors.

All of which can reduce the resonant length to very slightly less than the theoretical maximum value of 150/MHz metres for a halfwave dipole.

Or 492/MHz feet, pruned by a very few percent.

Behaviour versus the included angle of an inverted-V is slightly peculiar. As the included angle approaches zero (which nobody ever uses) the resonant length approaches that of an ordinary open-wire transmission line, 150/MHz again.

"Very slightly less" is of the order of 1 or 2 or 3 percent unless you have a VERY low antenna. Everybody's antenna is slightly different. Just keep a pair of pruning shears handy. Or bend the wire back on itself.

> distorting reality and ultimately reaching conclusions which are more
> and more wrong.

Consider an earlier example made up of lossless lines:

100W XMTR---50 ohm---+---one second long 291.5 ohm---50 ohm load

The voltage reflection coefficient at the load is 0.707. The power
reflection at the load is 0.5, i.e. half the power is reflected.

After steady-state has been reached, the XMTR has output 300 more
joules than the load has accepted. A smaller real-world experiment
will easily verify that it is a fact that all energy sourced that
has not reached the load must necessarily be confined to circulating
energy or losses in the transmission line.

Question: In the above example, where are those 300 joules of energy
located and what is happening to them?

We know that 300 joules is wave energy and RF waves always move
at the speed of light, i.e. they cannot stand still. So please
determine how much energy is moving and in which of only two
possible directions.

The knife cuts both ways. Ignoring the energy gives one a very
warped view of reality where TV ghosting cannot exist, RADAR
can't possibly work, there's no such thing as non-glare glass,
and RF energy just sorta slowly mushes side-to-side inside a
transmission line. Can you spell M-A-G-I-C?

> I strongly suggest forgetting completely about "forward" and "reverse"
> power.

Good way to condemn yourself forever to a non-understanding of
energy movement in a transmission line. If that's your choice,
be my guest but please don't try to pass yourself off as an
energy expert by ignoring energy movement.

Many authors of transmission line textbooks disagree with your
stance.

I know you consider it unfair to your position to bring up
the subject of TV ghosting but perhaps considering such would
enlighten you about EM RF wave reflection energy.

Or maybe you can just explain where the modulation energy was
hiding while it only apparently made a round trip to the load?

Rhil wrote:
"Is there any half-way decent indoor ant I can use on an old Hallicrafter S-40 B? I mainly want to extend peception for nighttime MW."

Satisfactory reception depends on signal to noise (and interference) ratio.

At night, diatant BCB reception is via the skywave which is reflected from the ionosphere. On reflection, both polarizations, horizontal and vertical are produced by the ionosphere. Only vertical polarization is sent by transmitters as the local audience is the only one that can be sold to advertisers. Vertical polarization propagates very well by groundwave beyond the line of sight, day and night. Horizontally polarized waves are not propagated by the groundwave at all. The earth short-circuits horizontal polarization.

Thus, a balanced horizontal doublet antenna will pickup the DX while rejecting local noise and interference which is overwhelmingly vertically polarized. Never mind that the antenna is much shorter than 1/2-wave. The S-40 has s lot of gain and can overcome low signal levels. Its big problem will be interference from undesired noise and interfering signals, much of which the doublet will reject.

Another antenna will produce the same benefits. It is the resonant loop antenna or loopsrick. It can be oriented to reject vertically polarized reception. It is also small and can be easily aimed to reject some horizontally polartized signals as well. I don`t see anyone rotating a BCB doublet to do thia, but it`s possible.

Loops and loopsticks are offered ready-made. I have no recommendations. In 1938 I had a new GE super console which came with a "Vee Doublet Antenna". It worked as advertised for mediumwave and shortwave.

Reg Edwards, G4FGQ has some free programs for those who would built their own loop antennas. He frequently posts messegages in this newsgroiup. Search for the URL`s you want. I hope I got Reg`s callsign right.

Best regards, Richard Harrison, KB5WZI

Hi Gang

I recently moved from a fairly flat state to one that is mountainous.

In getting to know the local area hams I have visited quite a few this past year.

Several of them have their ground mounted HF antenna's perpendicular to the grade of the land rather than vertical. In other words, the top of the antenna is roughly 90 inches off center toward the downhill side.

The only reasoning I have received thus far is it works better that way here. But not everyone adheres to doing it that way, all commercial antenna's are vertical.

What Gives?

TTUL
Gary

Yet another violation of Initial Conditions. Signal Generator outputs
are calibrated into a 50 Ohm Load. Another violation of Initial
Conditions is that Signal Generators do not source 100W.

In a signal generator equipped with a circulator/load, the signal
generator indeed does always see close to a 50 ohm load so, no
problem.

Highly.

All of the S-parameters I've ever measured were referenced to the ends
of the cables used to connect the DUT to the test equipment.

Absent concerns about SNR, I didn't give a rat's behind about what the
signal generator power was.

Where the signal generator was connected?

b1 = s11*a1 + s12*a2

The HP S-parameter Ap Note 95-1 sez:

|a1|^2 = Power incident on the input of the network
= Power available from a source impedance Z0

What was |a1|^2 referenced to?

Cecil,

It's a slow day, so I thought I might take some time to help you out of your dilemma.

Q: Where are the missing joules?

A: They are associated with the large standing wave supported by the mismatched terminations of your transmission line.

As I have pointed out previously, standing waves are not inert. The shape of the wave does not travel down the line, but the fields are changing, and the charges are moving. Within each loop of the standing wave the stored energy simply oscillates between magnetic energy when the current is high and electrostatic energy when the voltage is high. Very basic stuff.

The problem in your analysis is the initial axiom that RF waves always move. This is simply incorrect, and it leads to the dilemma you face. Traveling waves are fine if you do the math correctly, but the physical situation is in the form of a standing wave. The model results need to agree or there is a math error.

And as many people have pointed out, always add the voltages and currents first and only consider power at the very end of the analysis.

Since you are also an optics guru you might want to check into the details of laser cavity operation or Fabry-Perot etalon operation. These are highly mismatched systems with very strong standing wave components along with a little bit of net traveling wave. Definitely related to the problem you posed.

> circulator/line interface.

A circulator, being in general a three (or four) port directional device, might have some trouble buying into that logic. ;-) The crux of the phenomenological problem is that power does not flow or move, nor is it something that is reflected. Hence Roy's (and Reg's) suggestion that the voltages and currents resulting from the fields which propagate must be analyzed. From that analysis (which involves the fields, or V and I, propagating, reflecting, and interfering in both directions) one can determine the quantities of energy being absorbed by the effected dissipative loads in the circuit.

A transmission line circuit which includes a circulator w/load does indeed provide a mechanism by which a portion of the energy produced by a source can effectively be reflected from a mismatched load back toward the generator. On encountering the circulator in the reverse direction, it is then directed to the circulator load where it can be dissipated. In a lossey transmission line, that reflected signal will be attenuated and would in fact increase the total amount of energy the transmission line dissipates. The amount of energy produced by the generator increases by the amount lost to the circulator load and the transmission line. **Absent the circulator, those energy losses would not be realized - nor sourced.**

The argument that fields "have" or "contain" energy is misdirected and misapplied. Obviously one can measure a field at each of the electrical

outlets in his house even when nothing is drawing energy from those outlets. The potential to create a transfer of energy does not necessarily equate with a transfer of energy. A mechanism must exist which provides the conduit for a transfer of energy. It is that mechanism, and the nature of the source and the load which determine the amount of power being generated and transferred to the dissipating load.

Hi Richard,

Then that is dashed by his having trimmed the ends (presumably everything at the same height, and as such in a direction away from earth) and the multiplier shrank more. More likely the capacitance between the ends grew instead (corresponds to all factors observed).

Cecil,

Radio amateurs and "magic antenna" charlatans love to abuse Poynting vectors and the Poynting theorem.

The basic answer is no, it is not correct to say, "the power in an EM wave was [is] defined as ExH."

The Poynting vector, generally described as ExH, is the energy flow density. It has units of energy/area/time. While this may seem to be nitpicking it is essential to note that this vector is defined at a point, not for a "wave", and an integration (or summation) over the surface of a closed volume must be performed before one can say anything about power or conservation of energy.

In practical terms the Poynting vector ExH and the Poynting theorem have little utility for radio amateurs.

The "large standing wave" is associated with a an EM forward wave
traveling at the speed of light superposed with an EM reflected
wave traveling at the speed of light. Please give us an example
of an EM standing wave that is not composed of superposed EM waves
traveling in opposite directions at the speed of light.

What you seem to be saying is that two similar vehicles traveling
in opposite directions at the same speed don't possess any net
energy. Try standing between them when they crash and get back
to us.

> As I have pointed out previously, standing waves are not inert. The

> the current is high and electrostatic energy when the voltage is high.
> Very basic stuff.

Very magic stuff. EM waves simply cannot slosh around side-to-side
in a transmission line. EM waves must move at the speed of light or
else the theory of relativity is wrong. You are mentally lumping
things together in your mind when they are not lumpable together in
reality, i.e. your thoughts don't match reality.

The only time two EM waves traveling in opposite directions interact
is at an impedance discontinuity. All other interaction exists only
in your mind, not in reality. In a constant Z0 environment, EM waves
traveling in different directions pass like ships in the night.

> The problem in your analysis is the initial axiom that RF waves always
> move. This is simply incorrect, and it leads to the dilemma you face.

Please give me an example of just one photon that doesn't move at
the speed of light. You will have proven the theory of relativity to
be incorrect.

> And as many people have pointed out, always add the voltages and
> currents first and only consider power at the very end of the analysis.

Please don't pass yourself off as an expert on a subject where your
only recommendation is not to think about the subject. It reminds me

of the priests who put Galileo under house arrest.

Cecil,

Fine.

My method solves the problem. Your method leads to endless threads on RRAA.

Have it your way.

Now THAT makes sense! I was worried that at the rate
I observed the nnn/f formula decline, your average 10m
dipole would be stupidly short!

And, for the record, I never touched the height of the feedpoint
or the angle of the legs. Instead of tying to the tips of the legs,
I attached the guy lines (heavy duty natural twine) about 8" up
from the ends. That way, I could trim the ends without having
to redo the supports. I wrapped the twine around the ends to
keep everything straight.

So, only 2 things changed - the height of the ends (10') and the
length of the legs.

Thanks everyone for the ideas.....

But energy does flow and move and is something that can be reflected.
You can easily see the energy packets using a TDR. Without energy,
those pulses wouldn't exist. The energy is obviously in the pulse,
where the voltage and current are.

And joules of energy flowing past a point is joules/sec, i.e. power,
by IEEE definition.

Incidentally, how do you explain the Poynting Vector and the Power
Flow Vector?

> The argument that fields "have" or "contain" energy is misdirected and

A lot of people will be surprised to discover that their electromagnetic
ExH and ExB values are "misdirected and misapplied".

Since NEC cannot model a sloping ground, just try modeling a leaning vertical, and see how it effects the pattern. I seriously doubt there would be much difference. Certainly nothing you would notice.

Rate of energy flow through an area? Sure sounds like joules/sec
(power) to me. The IEEE Dictionary agrees.

> In practical terms the Poynting vector ExH and the Poynting theorem have
> little utility for radio amateurs.

I particularly like Johnson's treatment where the forward power
and reflected power have separate Poynting Vectors. :-)

A quote from Ramo & Whinnery's, _Fields_and_Waves_:

"... it is often convenient to think of the Poynting Vector as
the vector giving direction and magnitude of energy flow at any
point in space."

Source record: 85901

There's good reason for confusion.

Resonance is defined as the frequency at which the reactance is zero.

Antenna resonance is the frequency at which the feedpoint reactance is zero.

At the input end of a feedline, resonance will occur at the same frequency as antenna resonance only if the antenna resistance is the same as the feedline characteristic impedance, or if the feedline is a multiple of a quarter wavelength (yes, quarter) long. So resonance at the input end of a feedline is often at a different frequency than antenna resonance. (You could call that "antenna system resonance".)

The reading on an SWR meter is a function of the both the resistance and reactance of the load presented to the meter.

As the frequency changes, both the feedpoint resistance and reactance change. So if the resistance is closer to the SWR meter's Z0 when there's a slight reactance, the SWR meter reading at the feedpoint can be better than at resonance, when the reactance is exactly zero. When measured at the feedline input, there's the additional factor of impedance transformation that can modify the reactance and therefore resonance.

In practice, though, the point of minimum SWR is nearly always very close to resonance, at the antenna feedpoint. This is because for most antennas, the reactance changes much faster with frequency than the resistance does. And, when the feedpoint resistance is roughly equal to the feedline Z0, the transformation by a mismatched feedline isn't extreme, so again the point of minimum SWR is usually close to resonance. Where you're likely to see a noticeable difference between resonance and lowest SWR is with antennas with several coupled elements (where feedpoint R can change more rapidly with frequency), or severely mismatched feedlines, like when using open wire line to feed a dipole on several bands.

In the end, it really doesn't matter. There's nothing at all magical about resonance, so there's no need to try and achieve it. What you're usually interested in doing is matching the rig to the input of the feedline, and the common measure of the quality of that match is the reading on an SWR meter. So the common, and valid, practice is to prune the antenna for lowest SWR meter reading. If you do that, there's no need to worry about where resonance might be.

I had a hunch about that. But I can't always parse your sentences into
the form of a concrete idea. Usually an interesting read though. ;-)

That's absolutely right. Not all of us do. When some of us have a
question about something, we respond by flinging poison tipped daggers
at those who, in the persuit of a common interest, try to help us
achieve a more cogent understanding.

Your method doesn't begin to solve the problem of tracking
the energy through the system. In fact, it specifically avoids
tracking the energy. My method has made a certain amount of
progress in the direction of understanding energy flow. The key
seems to be that for every case of constructive interference,
there must exist an equal magnitude of destructive interference,
as asserted by Hecht, in _Optics_.

This can easily be done with the free EZNEC demo program available from http://eznec.com. Here's a step-by-step for the demo or any other EZNEC v. 4.0 program:

1. Open example file Vert1.EZ. (Click the Open button, enter Vert1, then click Open in the file selection window.)
2. Click FF Plot to generate a 2D elevation plot of the vertical antenna.
3. In the 2D Plot Window, open the File menu, select Save Trace As, enter a name in the blank box, and click Save. You can close the 2D Plot Window to get it out of the way.
4. Click the View Ant button so you can see what you're doing.
5. Click on the Wires line in the large white window to open the Wires Window.
6. In the Wires Window, open the Wires menu and select Rotate Wires. (This feature isn't available in EZNEC v. 3.0 or earlier versions.)
7. In the Rotate Wires dialog box, make the following changes:
Rotation Amount: Enter the angle of the ground slope, and change the direction to CW (to simulate ground sloping down to the right)
Rotation Axis: Y
Then click Ok. You'll now see the tilted antenna. (The rotation will seem to be CCW, but that's because we're looking at the Y axis in the minus direction.)
8. Click FF Plot to generate a 2D plot.
9. In the 2D Plot window, open the File menu and select Add Trace. Enter the name of the plot of the vertical you saved earlier and click Open. You'll now see the plots of the vertical and tilted antenna superimposed.
10. If you'd like to see the dB difference between plots at any elevation angle, click the name of the recalled trace near the upper left corner of the plot window. The cursor will jump to the recalled trace, and the difference in dB appears as the bottom line of the right column in the data window below the plot. (This feature isn't available in EZNEC v. 3.0 or earlier versions.) If you don't see the data window, open the View menu and click Show Data. You can move the cursor by dragging it with the mouse, or with the arrow keys.
11. To see what the patterns would look like when the ground is tilted, print the plot (File/Print Plot), then rotate it clockwise by the angle of the ground tilt. Note that this assumes that the ground is flat and continues forever at the tilt angle, which of course can't be true. But it'll give you a good general idea of the effect of tilting the antenna.

If you get confused about how the plot is oriented relative to the antenna, go to the View Antenna display. Open the View menu, select Objects, then check the 2D Pattern box. This will superimpose a correctly oriented 2D pattern on the drawing of the antenna.

I did the experiment using a 30 degree tilt, and found a difference of 1.31 dB at an indicated elevation angle of 30 degrees. That would be at the horizon, taking into account the ground tilt. At an indicated elevation angle of 40 degrees (10 degrees above the horizon when ground tilt is considered), the difference is 1.77 dB. You can modify the ground conductivity and permittivity and repeat the experiment to see how this changes with different ground types.

Variometers are variable inductance coils.
There are two solenoids, one rotating inside the other.
Maximum inductance occurs when the two coils are in phase.
Minimum inductance when in antiphase.
Advantage - no switches.

DO NOT USE IN TRANSMITTER HIGH POWER CIRCUITS !

The whole length of wire is in circuit at all settings of the variometer.

Consequently as the inductance decreases the wire resistance remains constant.

So coil Q falls to very low values at small inductance values. i.e., at the high frequency end of the tuning range - where higher losses and an increase in temperature are already at their worst.

If the two coils are of similar sizes then Q can fall to near zero at low inductance settings.

Some variometers have the inside coil much smaller than the other. The inductance range is relatively small. The reduction in Q may be acceptable for low power applications and receiving purposes.

But the motion of the two coils, one inside the other, built into a working transmitter would fascinate visitors to the shack. An attraction quite capabable of overcoming the disadvantage of a ridiculous low Q at 30 MHz. It's even better than watching one set of 500pF capacitor plates slowly disappearing inside the other.

Here in the U.S., where conspicuous excess is widely considered a virtue (big guns, big trucks, big bellies, big antennas, big power. . .), you'd surely have to include a fluorescent tube suspended in the middle. It's especially important now that 866A's have become passe.

(I have fond memories from my childhood of a neighbor ham, ...BFB -- 'Barrel Full of Beer', who ran a kW -- at least -- of AM into a lazy H antenna which had a 4 foot fluorescent tube at each of the 4 wire ends. It impressed me as being really cool -- but then I was 11 at the time.)

Hi All,

This is a pretty radical slope. The one I lived on was closer to
20-25 degrees and it was (with low brush) a bear to climb (and to fall
without holding a rope for balance). When I do the trig for 30
degrees and stand with my feet one foot apart, shoulders and hips
aligned with the slope, that leaves one foot 7 inches higher than the
other. That's gonna take some stilleto heels. ;-)

That aside for the heartier cragsmen, this also presumes (from EZNEC's
propensity for a flat earth far field model) that the slope is infinte
(or a pretty tall hill indeed). Gee, on that hill everything must be
line of sight anyway! Who needs skip?

But then, no one lives in the valley. :-(

An excellent description, Roy.

There's a minor omission. You omitted to say that the SWR meters is
redundant because the actual reading is disregarded. There are other
reasons of course. Only a TLI is needed.

Every thorough discussion of the Poynting Theorem stresses the caveat
that Gene poynted out.

Born and Wolf does observe that the Poynting vector is adequately
defined as the "density of the energy flow", "the amount of energy which
crosses a boundary surface per second a unit area normal to the
directions of E and H." They add however:
"It should be noted that the interpretation of S as energy flow (more
precisely as the density of the flow) is an abstraction which introduces
a certain degree of arbitrariness. For the quantity which is physically
significant is, according to (41) [an expression for the rate of change
of energy within a volume], not S itself, but the integral of S . n
taken over a _closed_ surface." Emphasis on 'closed' is mine.

They also point out that the integral of the Poynting vector over an
arbitrary volume which contains no radiator or absorber of energy, or
where no mechanical work is done, is equal to zero. They cite
conservation of energy as the directive.

No, the SWR meter is useful in determining the quality of the match. I
was careful to say "SWR meter reading" to distinguish it from the SWR on
a transmission line.

Richard,

Your point is correct of course, but I must highlight an ASCII-based spot of confusion in my post.

Both area and time are in the denominator. I was sloppy in writing the equation.

energy / (area * time)

Of course the area is still there, and it is an energy flow 'density'.

But hey, what's a few missing units among friends?

73,
Gene

========================================

No! They just keep walking in the same direction. They have inherited a gene for sensing contour lines, never failing to get to where they want to be.

Hannibal, around 219BC, being unaware of genes in those ancient days, considered mountain goats could be useful on the famous crossing of the Swiss Alps on his way to Rome. But on second thoughts he decided to use elephants who, as you know, walk trunk-to-tail. Neither he nor the elephants quite made it to Rome.

I'm surprised that you don't know that energy/(area*time) is the
same as energy/(time*area) which is watts per square meter. The
IEEE Dictionary certainly knows that.

All that says is: if the flowing energy doesn't change, it hasn't
been dissipated or radiated. The energy is in the process of being
losslessly transferred from one place to another with joules/sec
passing an infinite number of points in space. From _Optics_,
by Hecht: "The energy streaming through space in the form of an
electromagnetic wave, is shared equally between the constituent
electric and magnetic fields. ... We now make the reasonable
assumption (for isotropic media) that the energy flows in the
direction of the propagation of the wave."

Source record: 85836

The quality of the match is NOT the SWR on ANY line. Quality is the degree
of conformance to specified requirements. Or how closely the transmitter
load matches the required value.

The meter does NOT measure the SWR on the line between itself and the
antenna. It does NOT measure the SWR on any real line. If only because no
other real line exists The meter is redundant.

As discussed elsewhere, other quantities which an SWR meter purports to
measure are Forward and Reflected power, both at the same place and same
time. Which are just as imaginary as the transmission line the meter assumes
they exist on.

Imaginary quantities can be useful at times. But at least the name of the
imaginary number "j" does not cause anywhere near as much confusion about
what is really happening as the name "SWR Meter" does. Witness the
arguments amongst otherwise sane, logical, intelligent, educated people.

Hi Jim,

You were desirous of "value added" writing, I believe. The
explanation and Gene's observation that this vector is not about power
has more correlatives in radiation, of the observable kind. We may as
well tread into the optics side of the family as long as we are here.

The same area bounded expression for light is Lux whose definition is
Lumens (power or energy/second) per square Meter (area).

Lumens are printed (mandate of law) on every box of light bulbs.

[Daggers fly here]
Unfortunately our resident Optical (sic) wizard here, has never been
able to express ANY answer for his Optical pronouncements in ANY
Optical term, not even Lumens. Bringing such topics as Optics to the
discussion and leaving them adrift demands sneers in response to such
babbling sophistries.

Hi Gary<

Not so much that you would notice. It might upset tuning, but even
there it is a toss up. About the only screw up would be that the
lower element goes to the coax center conductor, and your coax shield
makes contact with it while both drop in vicinity.

Hi Walt,

A ground wire wouldn't be advisable, I wonder if you have anything
metal (that actually went to a ground in the set) to attach to anyway.
Sounds like your set is powered with a two prong, polarized plug and
the case is probably plastic as a safety consideration.

As for an external antenna - again there seems to be no provision, nor
expectation that this is even an option. As it appears it is
intimately tied into the power cord, trying to preserve that feature
and/or attaching your own connection may be lethal.

About the only remaining choice is for passive coupling where you take
an external antenna, bring its lead down and wrap it several times
around the cord (or tape it along its length) and hope. Leave all
insulations intact, this is simply a function of proximity, not
connection. Even this is a spin of the wheel.

That's the way the Mic input for PC Sound Adapters is wired. The microphone for PC's has a STEREO
plug with the signal on the RING only. I found out the hard way that a microphone with a MONO plug
will short out the MIC input.

TenTec probably wired it that way so that a PC microphone would work.

The advantages of which Moxon wrote are for *horizontal* polarization only. If the antenna height above ground is correct, the ground reflection can reinforce low-angle radiation in the downslope direction.

But Moxon also shows specifically that there are *no* such advantages for vertical polarization. The ground-reflected ray is lost at a high angle.

If it wasn't for the fluorescent tube I taped to the wire going out
the back window of my bedroom to a neighbor's tree yonder I never
would have found the hot spot tap on my 80M ARC-5 tank coil. 1953 age
16? Precocious I was not and I still ain't. I forget. But then I
discovered that tuning up by maxing the output of Mrs. Chandler's, the
next door neighbor the pore thing, bathroom lamp was a more better
route to go than the fluorescent tube when it got down to flooding the
neighborhood with RF then tuning around with the S-40B for a contact.

We're ALL nuts.

You probably won't be able to notice any difference, as long as the coax doesn't touch the lower element. Spacing of an inch or two is all that should be necessary.

I have a vertical dipole for 10 Meters. The lower section consists of a ~2 inch pipe and the coax is run inside the pipe, to the center of the dipole. The upper section is a thinner rod, because it's not needed for support like the bottom section is. Each element being a different diameter poses some problems in matching, but in the end, it works very well.

If your living in an apartment or need to keep things stealthy, for
appearance sake, a good antenna can be had by connecting to a close by
travis rod. You may have one that leads out to a balcony or patio or just
on a big bay window. I snake a thin wire along the molding, from my
receiver, up to the travis rod. The longer the rod the better. Because
of paint, electrical connection between the expandable sections can
be a little problem, but that can be fixed by inserting some small screws.

It's not.

The power input to the transmission line is the instantaneous power,
V(t) * I(t), averaged over one cycle. This is the value indicated by a
classic AC wattmeter used in the power industry. The Bird wattmeter
indicates a so called 'forward' and 'reverse' power, neither of which
are truly power, and have been discussed ad infinitum in this newsgroup.
The difference between the 'forward' and 'reverse' reading on the Bird
wattmeter is equal to the power entering the transmission line.

It can easily be proven that the energy in the forward wave that
has not yet been reflected plus the reflected energy is still in
the transmission line. It can be proven, using TV ghosting, that
the reflected energy has made a round trip to the load and back.

It sure would alleviate the confusion if everyone would say,
"... is equal to the net power entering the transmission line."

re dB:

If one is measuring the losses in a 1/4WL stub with the following
configuration using a signal generator equipped with an ideal
circulator and circulator load resistor (SGCL):

SGCL----1/4WL stub-----

What are the losses in the stub in dB? :-)

Thanks for the info, but I already have the EZNEC demo. It does seem to be an excellent program, providing a low cost antenna modeling tool. I have been using another version of NEC for quite a few years and, to be honest, I prefer to work directly with the NEC cards. I feel lost if I cannot get in and edit the lines of code. I must admit I often use some of the additional program features to check if I have the correct card sequence, and also for tag rotation. I can also use any card listed in the NEC User's Guide.

Fact is I was not that interested in actually modeling a leaning vertical, although the problem is trivial. Now that you have done it, I may give it a try to see if I get the same results. Assume you used a slightly elevated radial ground plane with the S/N ground model applied.

Regards,

Frank

Source record: 85849

Hi Chuck

At least we have one sane person in the group eh!

I moved from St. Louis to Knoxville last year, as of yet I have not installed my HF9V here, in St. Louis it was mounted vertical on flat ground with about 3,500 feet of radials.

The only logical place for me to install my antenna is some 100 feet below the top of our hill, because of the radial bed. The grade of the hill is roughly a 30 inch average drop every 10 feet at the top of the hill.

Unless I build an elevated counterpoise that would have one side of it about 20 feet in the air, how would the underground radials affect the operation of the antenna if it is vertical?

Of the hams I have spoken with, those that have theirs vertical say there is no difference whether the antenna is vertical or not, and they should be mounted vertically.
Of those that have theirs leaning perpendicular to the grade line, they claim they could not communicate with certain stations when their antenna was vertical, but can with it perpendicular.

Although Knoxville is considered to be in a Valley, my home is situated on the north slope near the top of one of the foothills, but my property does go to the top, unfortunately, a little too far away from the house for the VHF/UHF, but it is roughly 30 feet above the crest of the hill, 60 feet above ground level at the shack.

I guess I could install two separate mounts, one vertical and one perpendicular and try both ways, but retuning those HF9V's especially when you have the 160 coil is a real nightmare.

FWIW: I cleared a line through the woods to run some dipoles. My first installation I mounted the dipoles horizontal with the grade line. But after putting up the VHF/UHF tower I moved many of the dipoles upward so they are closer to level. On the higher bands I did notice some difference, but on the lower bands they seemed to work about equally as well.

It seems all the 10 meter paper chasers have their ground mounted antennas perpendicular to the ground, while serious hams have theirs all mounted vertically.

Even those hams who live in the bottom of the valley have no trouble with HF communications, but those on top of hills often use large

beams and yagi's to take advantage of their prime location.

I have no antenna restrictions at my new home here, Yeah, other than what the FAA dictates regarding lighting if they are over a certain height.

TTUL

>possible directions.

Dear Cecil,

Here's my guesses -
The 300 joules of energy decays at a particular rate - i.e., in a certain interval of time, 63.2% of it will have been converted to and become dissipated as heat. During that same time interval,Ti, there will be an equal amount of energy introduced to replenish the amount lost. In other words, there will be a continuum of energy transferring into the transmission line to exactly make up for that lost in any given period of time.

Eventually, someone will disconnect the source generator at time T2. However, the load will continue to receive energy for a length of time, Ti, at which point roughly 63.2% of 300 joules of energy will have been dissipated in the load. If we wait long enough, 99.9% of the 300 joules will have been dissipated, but it will take forever for the last little bit to disappear.

It kind of makes you think in terms of "life everlasting", doesn't it?

73,

Bob, W9DMK, Dahlgren, VA

Yep, the point is that the *net* energy in the transmission line will
remain at 300 joules during steady-state. The transmission line is one
second long and the source is sourcing 100 joules/sec. That means that
200 joules of "extra" energy is being stored in the transmission line.
The forward power is 200 joules/sec, 100 joules/sec higher than the
source power. The reflected power is 100 joules/sec. There is exactly

where the 200 joules of energy are stored - half in the forward wave
and half in the reflected wave whose superposition results in the
standing wave.

It probably gets close enough to zero for government work.

Did you see my question on another posting? If one hooks up a 1/4WL
stub to a signal generator, what is the dB loss in the stub? It might
have something to do with your original posting.

Instead of messing about calculating the additional loss due to SWR and then adding it to the matched loss, I've just had a wonderful idea.

Why not calculate the actual line loss directly and solve all your problems at one fell swoop.

> propagate in any fashion, at any wavelength.

I know that's the physicists view, but some engineering views
are slightly different because of a differing definition of
"power". Let's say we have a one second EM pulse containing one
joule of energy traveling along a transmission line with three
joules/sec measuring points. For one second periods in succession,
we will measure one watt at the measuring points. In each case,
the one watt is the same one watt, displaced in time, being
transferred to the load. That one watt appears at the first
measuring point, then at the second measuring point, then at
the third measuring point, and finally heats up the load. It
certainly appears to be associated with the pulse moving from
the source to the load.

That's the way a lot of engineers deal with power, including
all the power company engineers that I know, and that's the way
the IEEE Dictionary deals with power.

Your "tree falling in the forest making no sound" concept
may not be the best approach for the real world.

Cecil,

I am glad to see you have come around to the correct view that the "extra" energy is stored in a standing wave.

Now if only we could convince you that mathematically, physically, and in "reality" there is not the slightest bit of difference between individual wave components and their superposition result then there would be real progress.

Oh, by the way, is there some reason you highlight *net* energy? Is there any other kind? Energy is a scalar, so numerically it can be only positive or negative, with no phase angle or other vector properties. Unless part of the energy in your transmission line is negative the net energy would be the same as the gross energy. (Not including sales tax and shipping charges.)

I am well acquainted with the concept of negative energy when describing atomic structure, for example, but I have not heard of negative energy in transmission lines. Can you explain the distinction you appear to make?

Never have I ever budged from the view that the "extra" energy
is stored in the standing wave components, i.e. in the forward
wave and the reflected wave. What I object to is your merging
of the forward wave and reflected wave as if they were some sort
of homoginized energy. You can prove your beliefs by providing
an example of a standing wave not composed of the superposition
of a forward wave and a reflected wave. I have offered that challenge
before and nobody has stepped up to the plate. Perhaps, you will
be the first. I await with abated breath.

> Now if only we could convince you that mathematically, physically, and
> in "reality" there is not the slightest bit of difference between

> would be real progress.

What you are arguing is that there is no difference between a husband
and a wife. They are just two components of a family who merge into
a single entity so either or both may be male or female. Sorry, Gene,
that's not my view of the world. IMHO, it is the *components* that are
important. IMO, you liberals are trying to destroy science and society
all at the same time.

> Oh, by the way, is there some reason you highlight *net* energy? Is
> there any other kind?

Of course, there is another kind of energy besides net energy. Is there
any difference between a wife and a husband? They are both parents, so
you liberals would argue that there is no difference between them. I
simply don't agree with you.

> I am well acquainted with the concept of negative energy when describing
> atomic structure, for example, but I have not heard of negative energy
> in transmission lines. Can you explain the distinction you appear to make?

It's a convention, Gene. I'm surprised you have never heard of it. ExH
traveling in one direction is positive. ExH traveling in the opposite
direction is negative. The Z0 of a transmission line forces the E-field
to H-field ratio to be Z0, i.e. forces the forward voltage to forward
current ratio to be Z0 - and the same for reflected current. One of my
references shows a Poynting Vector for the forward power and a separate

Poynting Vector for the reflected power, i.e. husbands and wives are not interchangable!

On the contrary, many of the pure-physics-oriented posters to
this newsgroup have alleged that the IEEE Definitions are Bull$hit
and are to be ignored. Check Google if you don't believe it.

The IEEE Definitions are what engineers abide by. Of course,
the disciplines of physics and engineering are certainly at
odds with one another. For instance, engineers have an altogether
different view of what "work" is, compared to the physicists.
Physicists say no work is done if the starting line and the finish
line are the same for a marathon. Engineers will say: "Then why am
I so friggin' tired?"

The POWER engineers at a POWER generating station operated by
a POWER company simply don't buy into your pure physics BS.
They assume that POWER (joules/sec) leaving a generating station
will, after subtracting losses, make money for the company.

Thanks for the information and explanation, Roy.

I do agree that the error introduced by using an SWR minimum as a proxy for zero reactance would not alone account for Ken's results. I also agree that resonance is important here only insofar as it is a definitional element in the nnn/f = L formula. I understand the formula is an approximation. At issue was whether the approximation held constant over a frequency excursion of approximately 5%, not an unreasonable expectation. Ken offered measurements purportedly showing that the approximation did not hold over that range. I will try to show that the uncertainty in the reported measurements does not provide confidence in the conclusion that the "constant" has changed. Whether the "constant" actually changed, and if so why, does not concern me here.

Ken initially reported a change to the "constant" (i.e., 234) of 2.32 in going from 9.5665 to 10.1955 MHz by trimming the length of a dipole. He based this on his measurements of SWR used to determine resonant frequency and on his measurements of wire length.

What is the required precision in SWR measurement needed to determine resonant frequency?

An error in measuring the resonant frequency that would produce a "constant" error of 2.32, is roughly 0.097 MHz. For a 30 meter half-wave dipole, the feed-point SWR ranges from 1.35 at 9.97 MHz to 1.35 at 10.02 MHz, with 1.34 being the minimum at 10.0 MHz (from Reg Edwards' swr_freq.exe program). This SWR range corresponds to a frequency difference of 0.06 MHz. More directly, an SWR measurement error of 0.01 at the antenna could produce an error in computed resonant frequency of 0.06 MHz. Measuring at the end of a transmission line is not likely to improve this relationship.

So how likely is it that SWRs were actually read with precisions on the order of 0.01, when the measurements were taken hours or days apart? I can't do that on my Bird. I think only a digital SWR meter can provide that kind of precision. On a calm day. With no inherent lsd jitter. And would it be repeatable after hours or days between measurements? Try it on your antennas. In any case, to achieve the 500 Hz precision reported would require something like five significant digits of SWR measurement. Maybe in a lab with a cutting-edge network analyzer. The issue is not accuracy, of course, but whether SWR measurements of the required precision are feasible. Please, no lectures, folks, on how unimportant such SWR measurements are in normal practice. This is a very unusual application of SWR measurement.

What is the effect of errors in length measurement on calculated frequency using the formula?

For the length measurement, Ken reports a precision of 0.001 foot. That is 0.012 inches, less than 1/64 inch. I don't believe this kind of precision was achieved either. An inch in a 24 foot length of wire is actually pretty good, considering the difficulty in holding it taut without stretching it, etc. But a one inch difference will produce an equivalent frequency error of 0.03 MHz (by the formula).

Simply adding the 0.06 Mhz and 0.03 MHz errors gives a total uncertainty of 0.09 MHz, an amount roughly equal to that required to generate an error of 2.32 in calculating the "constant". I know, I know. These are not rms errors. But they're what we have.

In other words, no cigar for for showing that the "constant" changes by 2.32 when the frequency changes by five percent.

Perhaps someone can provide a more sophisticated analysis of the measurement uncertainty involved. Perhaps with a better analysis, we will find that we can all go out and measure SWR to within 0.01 so we can calculate resonant frequency to within 500 Hz. Yeah, I know all that precision is imaginary, thanks to umpteen digit calculators.

And sure, changing the height of the antenna ends could also explain a change in the "constant". At least the change would be in the reported direction.

So there it is! I looked at the problem and tried to understand where the data came from and how they were measured and how much confidence I should give them. Meanwhile, I missed the whole point of the exercise, which seemed to be hypothetical: if one were to do such and such and found that the "constant" changed, what might have caused it. That's what's great about this group. The rest of you pretty much thought about the question and went to what is probably the correct answer. Do the data Ken reported really support that answer? Who knows.

Gotta love this stuff.

73 to all and thanks for your patience on this tediously long post.

Chuck

# 3082. HF ANTENNA TO SALE - SOMMER ANTENNA XP707

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-03 23:05:26 UTC
From: Jos&#65533; Lopes <ct1cjj@mail.telepac.pt>
Message-ID: <41b0f136$0$32398$a729d347@news.telepac.pt>
Source record: 85779

I am interested to sale my hf antenna above mentioned that is in very good conditions.

Reason: need to renew and create a new set up of antennas.

Antenna: Sommer (DJ2UT Beam)
Model: XP 707
Bands: 10, 12, 15, 17, 20, 30 and 40 meters
Balun: The balun furnished with the Sommer antennas is a low-loss air core type using RG142 (BU) Teflon cable. The balun will handle 2.9 kW continuous output at 30 MHz with a loss of only 0.05 dB.

This antenna it still on my tower and working very well.

For price please send one email to:
fartolopes@mail.telepac.pt

The transports costs will be at the resposability of the buyer.

If you are interestes we can sed some actual pictures, and for all the informations
concerning gain and front/back, please go to the oficial site:
http://www.sommerantennas.com/beaminfo.html

I have only just now read this thread so I am ignorant of anything
that has been posted before. I just want to add that, using my MFJ-
259B, the minimum SWR is not usually at the same frequency as the
purely resistive reading. Draw your own conclusions from that
measurement.

Suggest that you take time to understand the difference between an unterminated Rhombic and a terminated Rhombic and get back to us.

Hint: The forward wave radiates in the forward direction. The reflected wave radiates in the reverse direction. The termination eliminates the reflected wave thus eliminating the reverse radiation. I'm surprised that you don't know that.

Hi Jim,

With absolutely no illusions that he can answer the following:

79 Lumens is emitted by a light bulb of 80% efficiency;

At 0.1 meters distance, it impinges upon a 1 square meter lossy pane
of glass of ND = 0.125 and 50% is reflected;

At a total distance of 10M boresight beyond that pane, how many Watts
centered at 555nM ï¿½15nM are found within one square centimeter?

If that is too hard, how many candela total intensity did we begin
with?

Sorry to hack just a very short piece out of context, but it's pretty fundamental to the whole issue. I'll try to comment on the rest later, as time permits. . .

chuck wrote:

> resonant frequency?
>
>. . .

There is no amount of precision which will make that possible.

The resonant frequency cannot be determined by measurement of SWR alone (or more accurately, by an SWR meter reading), except in one very special case: If the resistance at resonance is equal to the SWR meter's characteristic impedance, then a reading of exactly 1:1 indicates resonance at the SWR meter terminals. This is seldom the case for an antenna or antenna system. In other words, if the SWR meter reads 1:1, then the load it's connected to is 50 + j0, which is resonant (assuming a 50 ohm SWR meter). There's no way to determine resonance with any other reading or for any other resistance -- if the meter dips to, say 1.2:1 at some frequency, you can't know if resonance has occured at that frequency unless you have some additional information.

Again, in practice, the point of minimum SWR meter reading is often, but not always, very close to the point of resonance (at the SWR meter). And again, there's seldom any need to determine resonance.

Maybe so. Texas certainly does seem to have its own unique set of
physical laws. ;-)

"Physicists say no work is done if the starting line and the finish
line are the same for a marathon."

:-)
No physicist I know would ever say something like that. Only a gross misapplication of Newtonian mechanics and/or thermodynamics could lead someone to such a belief. For example, such a person might think that a ball thrown up into the air has had zero work performed on it after it returns to the hand which threw it. The fact is, it requires as much work to return it to the earth as it does to throw it into the air. (There are some interesting physics demonstrations on how this doubling of work can be used to interesting advantage.) But since in mechanics there is no such thing as negative work, total work is accumulative. Potential and kinetic energies are of course restored to initial conditions, but the conversion from one to the other does not ordinarily occur without some form of external 'help'. The misunderstanding is at least consistent with some similar misunderstandings that have been expressed with regard to the physics of power and energy.

With absolutely no prospects of a correct answer short of my own:
102dB

Think you can find how many Watts centered at 555nM ï¿½15nM are found
within one square centimeter now?

Tougher question: How many Lux? :-)

If you can't do Lux, you sure can't do Poynting math.

Hi Jim,

I bet you can!

Edison/Mazda style tungsten filament light bulb. Available at K-Mart
or Walton's or any of a million retail outlets, even in Texas. If not
in Texas, then heat a brandin' arn to incandescence (bet he can't tell
us what temperature for 555nM tho').

Please, folks, Optics is for the professionals. Don't try this at
home! ;-)

Cecil Moore wrote:

> . . .
> The IEEE Definitions are what engineers abide by. . .

If you believe that, you haven't had much contact with real, working engineers.

In my experience, the IEEE definitions are often way out of step with common usage by working engineers. Nearly none in my acquaintance look to it as an authoritative source. A useful guideline, perhaps, at most. I can easily see three causes for the deficiency:

1. The IEEE Dictionary covers an extremely wide variety of rapidly evolving specialties, including power, digital, fields, control systems, fiber optics, electronics, EMC, and on and on. It would be extremely difficult to cover all these disparate specialties accurately and in depth without a huge amount of input from working engineers in each specialty.
2. As far as I can tell, the Dictionary is put together by volunteers, which limits the time and effort which can applied to it.
3. The active membership of the IEEE largely comprises academics rather than working engineers. Academics are a poor source of information about common usage by working engineers. And, working engineers don't tend to "abide by" the dictates of academics, in my experience.

I don't have a recent copy of the IEEE Dictionary, but think and hope it's improved over the years. But I'm certain it hasn't come anywhere close to the point at which it's something "engineers" "abide by".

I believe we're comparing apples and oranges. When the coax goes through the grounded side of the "dipole", the antenna is called a sleeve vertical or some variation of that. This is quite different than a vertical dipole where the coax would be next to the grounded side. This would induce pattern distortion and likely rf on the braid of the feedline. Unfortunately I don't have a scanner but if you'd like, I can copy the pages that describe both of these antennas with radiation patterns, etc.

Ohms law is gonna put 20 amps on that wire (1000 watts / 50 ohms)
I would expect it to fail - probably at the connection points.
I think it would heat up, become brittle, and break.
If it was mine, I would want to upgrade to 16 or 14 ga. before putting a kw.
-- I've always used 100 watts or less, so this is not from experience - just
my opinion.
Hal

> Will I be better off with elevated tuned counterpoise wires?
> Any advice?

use Copper wire (as opposed to alum) - insulated or bare - your choice - I would pick solid insulated.
Someone on this group mentioned using a chain saw to make slots in the ground for radials - and it sounded like a good idea. Some used a modified edger and made it work. I suggest getting some asprin or ben-gay for the day after installation.
moles eat grubs - so don't disguise the radials as grubs and you should be ok.
If squirrels didn't eat my dipole, the mole should leave your radials alone - its the rule. :-)

OK, can't do Poynting math either. The answer to that last is:
15.7 mLux

Now, as to Jim's flippant response as to he knew how much power in the
555nM ï¿½15nM band is found within one square centimeter. His premise
that if it was a Sodium Vapor lamp, it has only one spectral line at
590nM. That would have lead to an answer of 0W. However, this is
only for a low pressure Sodium Vapor lamp. High pressure lamps have a
very strong 555nM line. At least Jim could walk the walk.

There are a myriad number of other terms, all Optical, that have
correlatives to RF that would make an Ox stumble along this path. One
crippling question would be: How much TOTAL power was radiated? :-)

If you can't do Power, especially with all these clues, talking the walk about interference is a side show in the carnival.

Cecil Moore wrote:
>Of course,
>the disciplines of physics and engineering are certainly at
>odds with one another.

That is nothing but an excuse for your own sloppy thinking.

When it comes down to fundamentals, physics and engineering must always agree exactly - because they are both working with the same physical reality. That is a bedrock principle, known and shared by all competent physicists and all competent engineers.

There's a reason why they call these subjects "disciplines", you know. Reality sets hard rules that you have to follow - or else you'll get it wrong.

The only differences between physics and engineering are the acknowledged and clearly understood approximations that each side has to apply in order to follow its own particular interests. Physics is most interested in knowing things, while engineering is most interested in doing things - but neither to the exclusion of the other.

If your ideas cannot make the physics and engineering approaches agree, it means that your ideas are wrong. That is a simple and completely reliable test.

And it's strictly *your* problem.

I' ve got 2-3 of those programs. Probably more than that out
there...SBFFT is a DOS DSP program that works real well for a CW or
bandpass/bandstop filter. You can notch, etc , up to six signals at
once, within the stock passband width you select. It's real good for
notching heterodynes, etc...You can cut just a tiny sliver, taking out
the signal, but leave all the rest. I use that for MW sometimes. I
have another DSP program for windows that the guy that wrote MMSSTV
did...It has NR modes, which SBFFT doesn't. Chromasound is pretty
good, but payware...If I use a radio which has DSP in it, such as my
mk2g, I have dual DSP if I want it. Even dual auto-notch, etc. But the
software on the puter is much more powerful overall than the simple
DSP in the 706. All the 706 has is auto notch and NR. Neither of which
I use much at all. Only bandpass filtering is really useful to me, and
most radios don't have it. BTW, all those programs have the various
spectrum graphs, waterfalls, etc... You can see what to notch, and
what freq , etc..Kinda like PSK...
One thing though...DSP is nice and all, and the filters are brick wall
steep, but you can still have blowby problems with near strong
signals, etc...DSP is not near as "bulletproof" as a real hardware
filter. I use both. Get the best of both worlds...As an example...My
830 is pretty good as it is. Variable bandwidth, CW filters, etc...Add
the puter DSP, and it's killer. But in reality, the 830 is good enough
as it is...I have DSP but I don't use it all that much. It's not that
practical to use. For example, my 706 doesn't have a CW filter yet,
and the DSP would be real handy. But the sidetone delay on *sending*
makes it nearly useless. Doesn't do any good to have a 200 cycle
filter if I get tripped up sending due to the delay...:/

I'd have to rig up a separate real time sidetone. And that then means I would prefer to mute the puter audio when sending...All that mess is too much hassle...I just get on my old 830 with it's rock solid old fashioned filters, and be done with it...And the receiver is usually cleaner to boot, as no artifacts or blowby..MK

>purely resistive reading. Draw your own conclusions from that
>measurement.

The question arises because a single measured value of SWR can be created by many different combinations of R and X.

This is one of those times when the Smith chart can help to see what's happening.

The Smith chart is simply a map, that happens to plot R and X instead of latitude and longitude. At school, you learned how to understand the different ways to project the globe onto a flat map. Each map projection gets one thing right, but is distorting in other respects. One projection gives correct distances, another gives correct areas, the great circle projection gives correct bearings... and then there's that orange-peel projection that only seems to be optimized for weirdness.

Well, the Smith chart is just another one of those map projections. Its useful property is that a circle, centred on the middle of the chart, connects all possible combinations of R and X that give the same value of SWR (for example, the "SWR=2" circle). The larger the diameter of the circle, the higher is the SWR, going out to infinity at the edge.

The centre of the Smith chart is the unique point where SWR=1: for a common "50 ohm" chart, that means R is exactly 50 ohms and X is exactly zero.

Now if you measure the complex (R-X) impedance of an antenna across a very wide range of frequencies, and plot it on the Smith chart, you will typically find that it goes in a series of orbits around the chart.

What you're hoping for is that the impedance plot of your antenna will pass right through the centre at your chosen operating frequency... or at least, that it will make a very close fly-by.

The frequency of the "SWR minimum" is the point of closest approach to the centre. The "SWR bandwidth" of the antenna is the frequency range across which the plot stays inside the SWR=2 circle (or whatever other SWR limit you choose to set).

The two halves of the Smith chart are symmetrical about the X=0 axis.
The "resonant" frequency at which the R-X measurement becomes purely
resistive is where the plot crosses through that axis.

But the point of closest approach is almost always *not* at the X=0
crossover. Except by coincidence, these two things always occur at
slightly different frequencies.

If I could draw a picture here, that would make it very clear. I hope
the word-picture has been clear enough.

Ian White, G3SEK wrote:
> If your ideas cannot make the physics and engineering approaches agree,
> it means that your ideas are wrong.

If you believe physicists and engineers agree on everything, you are
living in never-never land. It's difficult to find two physicists
who agree on everything - or two engineers. Witness the arguments
on this newsgroup.

Ian, there are 13 definitions of "efficiency" in the IEEE Dictionary,
each associated with a different engineering discipline. And that's
not counting the definitions of "efficiency" that exist in the
world of pure physics. Anyone who thinks a word has one and only
one definition that everyone agrees upon and encompasses all subjects
and all fields is clearly out of touch with reality.

For instance, I point to the definition of "power" in the IEEE
dictionary. Some posters on this newsgroup disagree with that definition
and that's from people who had the same textbook as I did in college.
Since that's the case, then of course, some of the ideas of engineering
and physics will disagree. "Power" for a power engineer working at a
power generating plant measuring megajoules/sec in a transmission line
simply does not have the same definition as "power" for a physics professor.

For resonance not to occur at minimum SWR, the orbit must not be a
circle centered on the pure resistance line. The 'R' in the R+jX
impedance looking into my transmission line changes much faster
around resonance than does any SWR circle.

Source record: 85813

an update on this little project...
I have tried various lengths from 32 to 42 feet and have settled on 32 feet.
I currently have 30 radials from 20 feet to over 30 feet. I am undecided to add more but can do so before putting in a new lawn next spring.
I am currently feeding it at the base with a 4 to 1 voltage balun and 30 feet of Belden RG8-U 50 ohm coax to a little ldg auto tuner in the shack.
SWR at the base of the antenna is 6 to 1 on 40 meters, 3.5 to 1 on 30 meters and drops from then on to 1.2 to one on 10 meters.
Even with the high swr on 40 meters (I plan on bypassing the balun for that band) an online coax calculator for my particular feedline indicates I am loosing at most 8-10 watts in the feedline. I have no way of calculating or estimating the losses in the little auto tuner or the balun and can only guess at the ground losses.
I am not too worried about 10 meter operation.
The antenna apparently works...if the band is only partly open I can work just about anyone I can read on psk on any band 40 thru 15 meters. Comparing it with my 80 meter twin led fed doublet, the vertical is doing its job rather nicely.
One little suprise...in the shack, without the ant tuner in line, the swr on 80 meters is quite low...below 3 to 1 on most of the band...wonder what causes that?
I have also given thoughts to raising the base of the antenna to 12 feet, and run 4 radials for each band, and am wondering if I would see much difference. I suspect the swr would be a bit different, but on the air??

Hello, Ian.

Yes, I was a bit hasty in citing Moxon.

But thinking a little more about this I wonder. Intuitively, and looking at Moxon's sketch, it would seem that the effect would be simply to rotate the vertical pattern by the amount of the slope. Aiming the pattern "down the slope" rather than "toward the horizon" does not seem to be a necessarily worse situation as Moxon suggests. Wouldn't that actually put more energy out toward the horizon?

Tilting a VHF ground plane antenna toward the horizon would be different because the vertical pattern at zero degrees is not attenuated by ground losses.

Chuck

Does the term 'uphill' guys imply that there are 'downhill' guys? Would
they be required? Be careful not to confuse the term 'downhill guys' with
old hams.

"Power" is just a single word, so it certainly does have to carry
several different shades of usage.

My point is that the competent engineer and the competent physics
professor understand that their different usages are still completely
consistent at a fundamental level.

I don't believe you understand the discipline that that need for
consistency imposes.

And then you want to think about modes. If you are operating SSB or CW,
the average power will be much less than 1000 watts.

That is true in principle, but the problem with a ground-mounted vertical antenna is that the angle of maximum radiation is fixed in relation to the ground. That means the angle of the slope has to be just right, and in general it also needs to be very steep.

With a horizontal antenna, you can vary the angle of maximum radiation by adjusting the height above ground. That makes it easy to apply the technique over a wide range of quite moderate slope angles, using quite modest antenna heights.

Changing the subject slightly, hams have become over-conditioned into wanting a "low" angle of radiation. It's true that we generally do need more radiation at lower angles than we can easily achieve; but until recently, we haven't had the information to understand what angles of radiation we actually *do* need.

Modern HF propagation programs give us that information. Not surprisingly, the optimum angle varies according to the path, the number of hops involved, the heights of the respective layers and the ionization levels... and hence the optimum angle also depends on the time of day, the season, and the year in the sunspot cycle. Recent editions of the ARRL Antenna Handbook analyse this problem in some detail, and show that "lowest possible angle" is not always the best objective if you're aiming to cover all possible cases.

The XM radio antenna are circular polarized patch antenna's. The easiest
way to make one is to use printed circuit procedures.
Unless you want to undergo the educational aspects of the exercise my
advice is to buy a commercially made antenna.

Hi Bob,

I notice that true to form, all the response in this thread were not
to your bench results. I trust you will appreciate hard
correspondence rather than the fluff.

The one thing (actually there are several) I noted was your having to
double the presumed line loss to make the numbers come out. Given
this injection (or removal) of 100% (or %50) of error, it stands to
reason that your bench, method or instruments need a attention.

The details as I've sifted from the postings:
Cable type = Columbia's number 1198 - not 9913.
Open circuit stub length = 5.334 meters
Frequency = 10.6 MHz,

Input Z = 0.57 + j 0.3 ohms.

The above details appear to have shifted in mid-stream to:
Cable type = RG-8/U line
stub length = 5.334 meters
Frequency = 30.0 MHz,
Open end termination = 4700 + j 0
Input Z = 2.45 -j15

I will skip the determinations of loss and SWR as being problematic as you indicate and simply go with your observations noted above, and summarized here:
Open end Vtermination = 100V @ 0ï¿½
Open end Itermination = 0.0213A @ 0ï¿½
Fed end Vinput = 29.2V @ -171.5ï¿½
Fed end Iinput = 1.917A @ -90.78ï¿½

I was puzzled to see what was initially a resonant stub now measured with an extremely high Reactance until I re-scanned the material to note the tripling of frequency.

What caught my eye was this load and certainly your leap of faith that it was wholly resistive, especially at HF for its size. This would be extremely unlikely even in a standards lab.

To make a measurement, the rule of thumb is to have instrumentation whose precision and accuracy exceeds the goal of measuring an unknown by 5 to 10 times. For really difficult tests (and RF is classic in that regard) 3 times is often the best you can achieve.

Let's look at that 4700 Ohm resistance. It demands that any instrumentation support a paralleling load of no less than 23.5K Ohms to 47K Ohms, or worst case, 14K Ohms. Let's simply ask about the family lineage of that 4700 Ohm resistance. It sounds suspiciously like a common (hopefully) carbon composition resistor.

If so, such beasties are rare if it is of the commercial variety, to not exhibit reactances due to spiral cut value trimming, or an end-to-end capacitance. Let's just say that you obtained a remarkable resistor, but it cannot escape this common parasitic capacitance which for the garden variety resistor amounts to 1.5pF.

At 30 MHz, this 1.5pF capacitance represents a reactance of 3.5K Ohm. This rather sweeps aside your specification for the load and replaces it with 4700 -j3537 Ohms. This is a big time source of error and does not even come close to the 3X requirement for the lowest accuracy. Worse yet, you haven't even added the bridging impedance of your measuring device which is certain to be on par, if not worse (you haven't identified your instrumentation).

Hope you are still looking forward to more fun. ;-)

I don't know about XM, but the Sirius antennas I have seen contain both a CP
sat antenna and a vertical terrestrial antenna. Also, they included preamps.

Can't do path loss, can't do Poynting math, can't do Power can you?

This was a give away. You needed only walk to your storage closet,
pick up a box of light bulbs and note the TWO characteristics printed
on every label - Lumens and Watts - to obtain a workable conversion
factor.

Seeing that I'm the only one likely to offer a correct answer:
10W

That answer is found IN THE FIRST LINE of the description!

This is all from a bulb the size of a christmas tree light. :-O

Dare I return to the original question:
At a total distance of 10M boresight beyond that pane, how many Watts
centered at 555nM ï¿½15nM are found within one square centimeter?

IF you could answer that, you MIGHT be able to do interference math!

What makes you think he is more right than anybody else?

Why should you be a judge?

Why do you seek support from paid book writers?

Do you lack confidence in your personal judgement and statements?

This small, slightly critical, message is intended to be in the most
friendly of terms. Applicable to many others in these threads.

I wish you the all best of both local stations and DX. And, as the festive
season approaches, an enjoyable Xmas holiday for both you and your family.

==========

Dear Ian, what has Moxon got to do with it?

Without personal experience how do you know you are not plagiarising and
further propagating old-wives' tales?

If you have personal experience do you need anybody else's support anyway?

Just state the facts on your own authority.

Or do authors all belong to the same masonic club which adds nothing to
veracity?

My only little axe is that I find it irritating when I read about quite
unnecessary references which add nothing but verbiage to the conversation.
Perhaps I'm funny or just impatient in that way.

But I'm sure you understand my non-technical interruption to this thread
with my appology. Reply not needed.

(PS: I have only vaguely heard of Moxon in these newsgroups. Never read him.
Not the slightest disrespect to him, or her, intended. But my own reference
bibles are restricted to Ohm, Ampere and Volta.)

Actually 1700 -j2258 Ohms

As you can see, this is the reason why open stubs are avoided.
"Knowing" the parasitic capacitance is problematic. The fringing
effect at the end is difficult to manage whereas a short is much
simpler to define and implement.

The terrestrial antenna is for those large city locations (NYC, Chicago,
etc.) where tall buildings can shadow the satellite signal and are
used to supplement the sat sig in these areas. They require local non
space based transmitters.
I used to sell these things.

==========

Just an addition -

You can't deal with Reflections without involving Distance, Velocity,
ECHO's, Place, and, above all, TIME.

Attempted steady-state analyses reduce to non-sense without involving TIME.

But it is a simple matter to relate power levels, one to another, dB-wise or
otherwise, at different PLACES and TIME.

All you guru's, old wives and experts on forward and reflected powers, real
or imaginary, should bear this basic, elementary stuff in mind.

Whatever happened to your primay education?

Power, work and energy are intimately related to TIME.

The self-educated kids living in South American underground Rio sewers,
subjected to culling by armed police, reduced to making a precarious living
be selling laced cigarettes, can do better.

But don't worry about it. Just continue taking your viagra. As for me,
tonight I'm on white, dry, Bordeaux, best consumed within six months of
purchase. And the French know what they are talking about.

## 3142. Wheel Antenna Plans

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-05 01:09:35 UTC
From: Matt <nospam_ng@fileholder.net>
Message-ID: <10r4o17g9jq4h29@corp.supernews.com>
Source record: 85739

Does anyone know where I can find some construction plans for a "wheel antenna" in the 33cm band?

Matt

# 3143. Converting the Antron 99 to 40m

Newsgroup: rec.radio.amateur.antenna

Not sure about moles.

But at a previous house with a pier & beam foundation, I had telephone wires running in the crawl space under the house, along the top of the dirt, and howling feral cats in heat chewed the daylights out of the wires. Broke my telephone connection.

Telephone guy came out and he asked what the hell kind of animals I had under the house. Said the wires were mangled beyond belief.

He installed a new set of wires up on the house walls, with the wires firmly stapled in place. That solved the problem.

I'm guessing the cats liked the flavor of the insulation.

Thanks for the correction - Don't know what I was thinking at 130 am
P equals I-square R ***of course**
I was treating it like volts * amps = P
and I was apparently confusing R with Volts or Amps

Dear Richard,
Each and every one of your concerns is deeply appreciated. I had
seriously about measuring that 4700 ohm resistor by itself for just
the reasons that you mention. The reason that I did not is quite
simple. The Resistance dial on the General Radio Model 1606B RF Bridge
only goes to 1000 ohms. C'est la Vie!

I could have chosen a much lower resistance to start with, but then I
would not have had the desired high SWR, which is critical to the
experiment. You might well ask why I made the switch from a 1/4 wave
open ended stub (at 10.6 Mhz) to the 30 MHz test using the same piece
of line. That was to get a high SWR and still have reasonable
confidence in the value without actually measuring it. Perhaps I
should use a capacitor instead. That's still a possibility. I am
thinking of doing it over with a measured 1 k resistor, and just
accepting the SWR of only 20:1. I don't think I have any low ohm
resistors that would give me something around 1 to 3 ohms and still be
low inductance - not from my parts box. Actually, I doubt seriously
that the capacitance effects are as bad as you are suggesting, but I
won't argue that without some additional measurements.

My reason for not going with a short circuit was even simpler. I
wanted a concrete value for a non-zero load power.

Regarding the artificial adjustment of the attenuation loss from
around 0.9 up to about 1.72 did not bother me at the time that I did

it, but I can see why it bothers an independant observer. I will have to do something about that, and perhaps doing it over with a 1 K resistor is the answer to all of that - so, here goes, and I will get back to you in a few hours.

BTW - this is becoming more and more academic, since I think the real mystery has been resolved, but there's nothing like getting it wrapped up with a proper ribbon.

>Does anyone know where I can find some construction plans for a "wheel
>antenna" in the 33cm band?

Depends which variant you're looking for.

One "wheel" antenna type is the halo, which is basically a halfwave
dipole bent into a circle, with the ends an inch or two apart (the
distance is an important factor in the tuning), usually fed via a
gamma match. Google for "2-meter halo" (a common variety) and rescale
the design as necessary.

Another variant is the "big wheel", which is three full-wavelength
loops (each bent into a third-of-an-apple-pie shape) fed in parallel,
with a hairpin inductor shunted across the common feedpoint. Older
editions of the ARRL VHF Handbook contain plans; I don't know about
the current edition.

Say la-la!

Hi Bob,

Good, you have a great piece of equipment, but the implicit question remains, what do you use to measure the voltage? That is going to be a serious load across even a 4700 +j0 resistor. Even X10 Scope probes would be a poor method.

>I could have chosen a much lower resistance to start with, but then I

Hardly worth the thought actually. The 1.5pF stray capacitance would be a coup-de-grace for the resistor, do you think you could find less capacitance (with or without the resistor) when there is probably already that much in fringe capacitance?

>won't argue that without some additional measurements.

It's better than sitting on the park bench with a box of chocolates and spouting the philosophy of optical interference. For that you get my Kudos.

Well, one way is to take your measurements and stick with the original attenuation loss and transform from the input to this 4700 Ohm load. Does the data suggest this load is closer to my hip shot guess? You have a reactance built into your results that is unaccounted for, but comes with this parasitic inclusion I offer.

>BTW - this is becoming more and more academic, since I think the real

It's all academic, Bob. When you have to take more than one exam (with questions that go beyond parallel parking) to pursue a hobby it's part of the turf. Owning a GR-1606 caps it.

Can't do path loss, can't do Poynting math, can't do Power, and can't
do interference math can you? A tape recorder can repeat equations.

This is pretty grim:
0.55 nW/cMï¿½

Which, of course, is accessible from the already provided path loss,
IF you could find the apportioned spectrum of the original Power.

This introduces yet another question that would go unanswered - but
Bob offers that rare, rare prospect of engaging in dialog that
contains actual hands on data, a treat in comparison.

Certainly not; most authors do value a cross-check on their own thinking
- and above all, a cross-check against reality.

I certainly do, because it's how I was trained.

The value of the major academic textbooks is that most of them have been
in the public domain for decades, and available for critique and
cross-checking and correction in later editions. If your own findings
don't agree with the pool of knowledge that's already out there, you'd
better have some strong reasons to hand.

In this respect, all amateur radio publications are in a lesser league.
They are still going through the process of critique and technical
clarification - marvellously accelerated by the Internet in recent years
- but they're not there yet.

>(PS: I have only vaguely heard of Moxon in these newsgroups. Never read him.

# 3156. Re: Oddity of ground mounted antenna's.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-05 16:56:42 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <10r6fe6352tquf7@corp.supernews.com>
Source record: 85753

From decades of looking at optimum take-off-angles (TOA) at HF for long paths, I have found that TOAs are rarely above 12 degrees and only occasionally below 2 degrees. This leads to the conclusion that if cost were not an issue and one could only put up one horizontally polarized gain antenna (Yagi, LPDA, or such), the antenna should be 2 to 2.5 WL high. At least one edition of the ARRL Antenna Book has the same conclusion.

A higher antenna starts to have nulls in the useful range of TOAs.

As usual, Ian has the right idea.

>> problems
>> at one fell swoop.
>
> What is the formula for the total dB loss?

I don't know of one, but here's a procedure which will get you the answer:

1) Determine the transmission line characteristics R, G, L & C at the
frequency of interest.

2) Determine the transmission line termination impedance (or admittance)
at the frequency of interest.

3) For convenience, define the excitation at the input to the
transmission line. e.g. defined voltage, current, or generator with
defined source impedance.

4) Solve the transmission line equation for both the voltage and
current, as a function of time and position, subject to the imposed
boundary conditions. Use any method you wish, though the usual approach
is the so called method of reflections where the complete solution is
taken as the summation of damped forward and reverse traveling waves.
Calculation of Zo and Gamma require knowledge of R,G,L & C.

The solution can be expressed algebraically in terms of hyperbolic
functions and will be found in any good transmission line reference.

Now known are v(x,t) and i(x,t).

5) Separately calculate the dissipative losses due to series resistance
and shunt conductance (or dielectric power factor) as follows:

a) The loss due to series resistance at any instant in time for some
section of transmission line, is i(x,t)^2 * R * dx, integrated over the
subject transmission line section.

b) The loss due to shunt conductance at any instant in time for some
section of transmission line, is v(x,t)^2 * G * dx, integrated over the
subject transmission line section.

c) The total dissipative power loss is the the sum of the time averaged series and shunt loss components, integrated over the entire transmission line length.

Consider:

The SWR (reflection coefficient at the termination) alone is not sufficient to determine the loss in general. This is an important concept to understand.

For illustration, assume the limiting case where the shunt conductance can be disregarded. This is a useful approximation for many transmission line installations used at HF where the SWR is reasonably low (<50). In such practical cases the losses will be dominated by series resistance.

Consider a short (<45 electrical degrees) transmission line terminated in a pure resistance which is much less than Ro. The standing wave pattern will be such that the current will be maximum, and the voltage minimum, at the termination. The losses can be calculated using the procedure given above.

Now consider the same transmission line terminated in a pure resistance larger than Ro such that the SWR is the same as previously. The current will now be minimum at the termination and the total dissipative loss will be considerably less than when the termination resistance is low, even though the SWR is identical.

Transmission line losses depend on both the actual load impedance and the transmission line parameters. Knowing matched attenuation (dB/length) and load SWR is not sufficient to calculate losses exactly. Any formulas using only SWR and matched transmission line loss are approximations and must be used carefully!

Feeding electrically short antennas with 50 ohm coax as is commonly attempted by amateurs on 80 & 160m can result in transmission line losses much larger than predicted using the simple approximations given in the amateur literature.

There is no stuff called "Wireman". There is a supplier of ham radio
antenna supplies called "The Wireman". I get most of my antenna
materials from him lately, and they're pretty good, including the
ladderline he sells. Specifically, what's the problem?

The open wire line from w7fg, by the way, is well made. I have a hank
of it, aand no complaints.

You are all floundering about like fish out of water.

The ONLY way to predict the performance of a small resistor at UHF is to treat it as a transmission line - starting with the simple dimensions of length and diameter.

L, C and R, and short-circuit input resistance versus frequency automatically drop into your laps with adequate ball-park accuracy.

As so-called engineers, if you can't measure it, such obvious arithmetical techniques should already have been included in your elementary analytical educations.

Spice (of which I have heard about only by reputation on newsgroups) is useless unless one already knows what it's all about beforehand.

My criticism is not personal - only of the western world's educational systems and insistent dependence on weapons of mass-destruction.

Of course, Bart's math is fine. Seems like there's a bit more to the story. The current may be less because the actual antenna impedance may be a bit higher than 50 ohms, but 50 is probably a reasonable figure for calculations, to be on the safe side. And Chuck's right that the heating may be much less because of the mode of operation.

But...what current would be too much? The RF resistance of the 26AWG wire at 4MHz is about 125 ohms/1000 feet, or about 3.06 times the DC resistance, at 20C. The DC current to get the same heating as a 4MHz RF current would then be about sqrt(3.06)=1.75 times the RF current--close to 8 amps, using Bart's calculated RF current. (It's actually a bit less as the wire gets hot and its resistance goes up, because the skin depth increases with increased resistance, but use 1.75 times for a worst-case.) Since the fusing current (current at which a wire in nom. 20C ambient will melt) is 20.5A for 26AWG copper, you're very unlikely to melt the wire, but it very well might get pretty hot, depending on actual operating conditions.

Suggestion: suspend a foot or so of 26AWG like you used in your antenna, with a weight on the bottom end to put similar tension in the wire to what you have in your antenna. Run a DC current through it, and see if anything bad happens (like getting too hot, stretching too much, or whatever). Use a DC current so that the heating will be similar to what you'd get worst-case with your antenna setup. Or use RF, if it's easy for you to do that...DC would be easy for me. Expect to get very similar heating if you use about 1.75 times as much DC current as what the RF current will be. So try about 8 amps for a worst-case test.

Cheers,
Tom

>> Cecil, when there are several different power levels at different
>> places in
>> a circuit, it is entirely up to you how you reference one to another
>> in dB.

> Now Reg, that just cannot be true.

It is true.

>Otherwise, there would exist no
> conventions.

Multiple conventions exist in all the technical disciplines. A well versed practioneer is familiar with the various conventions commonly in use and will choose the one most appropriate to the problem at hand. General terms such as 'gain' and 'loss' always require the context be carefully established before the term can be used with any precision. For example, dissipative loss in a transmission line is different from transducer loss, but both are often expressed in decibels. One relates to an actual ratio of two physically meaningful power levels, and the other is notional.

>It's a simple question: When you tell me that the losses
> in a transmission line with reflections are 2 dB, exactly what power
> are you referencing those losses against?

Reasonable question. Without knowing the context the statement is essentially meaningless.

>> Reflected volts - yes!
>> Reflected current - yes!
>> Reflected power - NO!
>
> Reflected volts and reflected current existing without any associated
> joules/sec????

Reg didn't say any such thing. The wave equation is usually expressed in terms related to the two complementary field quantities associated with energy storage. In the case of TEM transmission lines, the two variables are voltage, and current. The method of reflections (images) used to facilitate solution of the wave equation, utilizes the concept of voltage and current reflection coefficient respectively. These concepts are used to find the v(x,t) and i(x,t) without any reference to to power or energy. Once v(x,t) and i(x,t) are known, the power, v(x,t)

* i(x,t) can easily be calculated at any point x and time t. The
energy storage density can be calculated as i(x,t)^2 * L/2 + v(x,t)^2 *
C/2. As you might expect, the v(x,t)*i(x,t) is the derivative of the
energy storage density.

>I've heard of waves without any trace of energy before,
> Reg, but I certainly didn't expect to hear miracle metaphysics from you.

'Solving' the wave equation for TEM transmission lines usually means
determining the values of the v(x,t) and i(x,t) as a function of place
and time. Energy distribution, and it's movement, is easily calculated
from the knowledge of v(x,t) and i(x,t).

> Whatever happened to V*I*cos(theta) being power?

Hasn't changed; works for DC out to upper microwave frequencies.

>The power companies
> would be surprised to learn that they are not transferring any joules/sec
> to their customers.

Indeed they would. Who do you know who believes they are not
transferring energy to their customers?

Very nice, Tom.

Can we keep going with that?

Using the 8A dc assumption and the 40 ohm/1000 ft dc resistance of #26 AWG, we find that approximately 2.56 watts is dissipated in the first foot (less in subsequent feet). This assumes the current is linearly distributed in that foot.

To put it into intuitive perspective (not as neat as your proposed experiment, but a potential substitution of armchair hand-waving for actual work) we can say that the wire is dissipating about a quarter of a watt per inch near the center of the dipole.

Comparing that with the heat generated by a quarter watt resistor (at 1/4 watt dissipation)(larger diameter, shorter length) we are not likely to get 3rd degree burns from an incandescent antenna wire. Hi.

73,

Chuck

My point exactly, Bart. It is not up to me to define a new standard.

> Indeed they would. Who do you know who believes they are not
> transferring energy to their customers?

There are people who believe that energy being transferred past
a point in the transmission line is not power. However, the IEEE
dictionary says that power is the rate of generation, transfer,
or consumption of energy.

>
> Me

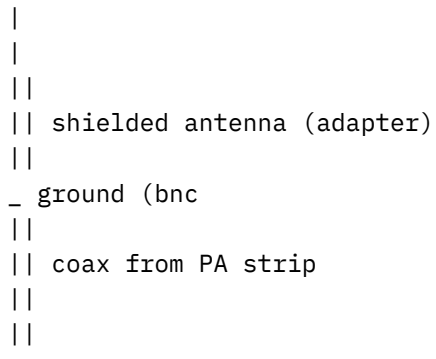
That is actually not quite true. On an HT, the transmission line ends
somewhere inside the radio. The SMA/BNC connector is part of the
antenna proper. If you add a sleeve (as the previous poster, "dixon",
says), you will be changing the antenna itself. ASCII schematic follows:

before:

```
|
| antenna
|
|
_ ground + bnc/sma
||
|| coax from PA strip
||
||
```

after

```
|
| antenna
```



And as we remember, "maximum radiation at the current maximum" (that is, the base of a classic 1/4 wave antenna), you are shielding the point of maximum radiation.

From a practical standpoint, you will probably be using a gain-retarded rubber duckie, and the 1 or 2 dB loss from even the worst adapter will be swamped by the -10 dB gain of the duck (that is "minus 10 dB gain"). The rubber-duck will make a 5 watt transmitter sound like a 1/2 watt one. Having another 1 dB of loss will make that 5-watt radio sound like 0.4 instead of 0.5. No big deal.

If you can keep your radio from being broken by using a quality adapter, and with a negligible loss in performance, I say, "do it."

If you are talking about squeaking out every last bit of signal, such as EME, the answer is "no". But if you are talking about walking around a hamfest on 2m, then spend a few extra bucks to keep from fracturing your antenna connector connection, which these days, most hams can't, or don't know how to, fix. <flames invited>

Your mileage may vary.

I've seen the other answers to this post, but no one asked this
question: why are you going to put a kW into a stealth antenna?

Before you do, you should do these three things: 1) be sure that you
have minimized all possible losses from your current antenna setup; 2)
be sure that you have a receiver that will pick a gnat out of the noise
(better use DSP), because you will be loud and everyone who answers you
will think you can hear them; 3) minimize any man-made noise sources in
your local area (sort of related to #2).

Remember, if you can't hear 'em, you can't work 'em.

All the best, and 73,
Dave

> TIA, Walt

Typically there is a metal clamp, either inside or outside the plastic case of the radio, around an inch long and 1/4" wide, that bolts to the power cord. This is a capacitive coupler. You can safely add a wire to that piece of metal, the wire being as long as you want. For FM broadcast, 5 or 6 feet should be adequate. Use an alligator clip instead of soldering (in case you change your mind later, or to avoid melting the power cord).

Email me directly if you want, and I will send you a JPG of what the one on my bedside clock looks like. It's old, but I doubt that it's changed much.

Source record: 85673

Bart, I don't doubt that your description of how to calculate line loss is correct.

But it's more simple than that.

The input and output currents (or voltages) of any line are very rigid and well defined. Regardless of generator internal impedance. Just as a transformer's input and output currents and voltages are defined.

Their ratio is even more simply defined, albeit in complex terms.

So when the line input RESISTANCE, regardless of input reactance, and the terminating RESISTANCE, regardless of termiating reactance, are known then the power input to power output ratio is easily directly calculated from I squared R.

The hardest but still straightforward part of the calculation is for the input impedance, Rin+jXin, for given line attenuation and phase shift, and for given terminating impedance, Rt+jXt.

The power dissipated in the line, although distributed in a highly complex manner along its length due to standing waves, is very simply Pin - Pout.

Throughout the calculations, things like reflection coefficients and SWR do not appear, You cant use them as spin-off benefits. What practical use could you make of them anyway? The calculations have already been done, finished, ended, caput!

>Has anyone ever found an efficient loft antenna - one that really works on
>all bands ?

Hi John, Any antenna that is efficient on all bands outside your loft will perform about the same if you put it inside your loft. (maybe not verticals) There will be some changes due to the metal that will be present in your loft, but the efficiency will not suffer much.
The obvious problem is how to stuff the antenna into the limited space. The most efficient all band antenna that I know of that could fit is a 130' doublet fed with ladder line and a tuner. You may not have 130' available so you reduce it to 100' without much efficiency loss. You could zig-zag it to reduce the space needed even more.
This gets me to what I did. I have a 2 story house with a 40'x30' attic. I put 100' of wire up there, and fed it with ladder line and a tuner. Works well on 80m-10m. Works all the electronics in the house quite well.

Dear Richard,

New Measurements -

I created a terminating load consisting of 4 composition resistors in parallel. That measured 4.3 + j0.65 AT 20 MHz. I then measured the input impedance of the 5.33 meter length of RG-8/U Foam coax terminated with the 4.3 +j0.65 ohm load at 20 MHz, and that was 5 - j7.1 ohms. The SWR at the load is 11.63 and the SWR at the input is 9.88.

Using a velocity factor of 0.745 and an attenuation value of .77, I calculated the theoretical input impedance of the coax with the above terminator. That gave a result of 5.17 - j7.3 ohms (theoretical). The SWR at the load is 11.63, and the SWR at the input to the line is 9.88 (theoretical).

In setting up the simulation, it is necessary to pick an attenuation and a velocity factor that are not only within the normal distribution for that particular coax but also give a reasonably good match with the measured values. In my opinion, the values that I used in the simulation are well within the normal distribution of values for this type of line, which has published values of VF=.8 and attenuation = 74 at 20 MHz.

The simulation also predicts the losses, and I used two different models for that calculation. Both loss models predict a total loss of 0.723 dB, which is 0.589 above the matched line losses based on the normal attenuation. The two math models used were as follows:

1) ITT Reference Data for Radio Engineers, 5th Edition, pages 22-8 and 22-9.

2) The ARRL Antenna Book, 17th Edition, page 24-9.

Based on the limited tests that I have made so far, the two models seem to give the same results. However, I am hoping to be able to conduct measurements on configurations that involve much higher SWR values. The immediate problem to be overcome is the measurement of such impedance values as will be encountered.

It depends on whether you are in Alaska, in mid-winter, at midnight, or in New Mexico, at midsummer, at noon.

The temperature rise will not do any damage, not even to birds. The reduction in efficiency due to increase in wire resistance will be insignificant. Think in terms of 0.001 S-units.

Just turn up the powe to 1 KW and see what happens, if anything. It won't fall down. The antenna length might increase by some fraction of one percent due to thermal expansion. But your tuner will not notice any difference. The difference is about the same as that between summer and winter,

Remenber that the wire has a very great surface area, over a length of many feet, to dissipate the amtenna losses - and in a cooling breeze. It/s only the relatively small antenna losses, roughly 100 watts, which have to be dissipated - not the full 1000 watts.

Most of the loss and temperature rise occurs in the middle half of the antenna. It is calculable but not worth the trouble. If it is enamelled magnet wire the enamel will probably not be affected. Enamell is accustomed to being in prolonged warm places.

The probability of doing any damage to anybody's property is less than winning the national lottery with only one ticket. You may consider making your antenna even more stealthy.

In general, the diameter of antenna wires is decided only on the grounds of durability in adverse weather conditions. Here in the UK we are quite fortunate - until Earth Warming tornados become more frequent.

I'd go with the 706MkIIG... the 703 is a QRP rig with a max output of 10
watts.

The TS50 is older tech, but still a decent rig. I run a 706MkIIG in my
semi, and have had no problems with the rig at all..

Antennas and tuners are a different story, though...

You can roll your own. Wire is cheap at Lowe's and Home Depot.
Insulators can be pieces of plastic irrigation tubing, also
cheap.

Greetings
I have been using balanced line for many years and am convinced of its virtues, particularly since I use a single tuned doublet for multiband use.
The question I have never been able to get a clear answer on is this; How critical is it for the balanced line to avoid metal objects? Specifically, I now use about 6 feet of LMR 400 coax from a Radio Works remote balun into my shack where I tune the antenna from either a manual tuner or the auto tuner in my FT920. In order for me to run the twinlead all the way into the shack there will be about 18 inches where the twinlead will share a portal that I constructed to get my grounds and other cables in and out of the shack. Now I always thought this was a problem area for twinlead, hence the use of the remote balun.
I am considering the purchase of a new tuner and was thinking I would like a Palstar Balanced Tuner. But can I use it? Would I be better of with a T match and a short length of coax to a balun, or would a balanced tuner be better even with the 18" or so of twinlead coming in close proximity to the other conductors?
I really can not bring the twinlead in without it crossing paths as I desribed.
Is a balanced tuner all that better than a T match anyway in terms of antenna performance or loss?
What say?
Thanks

I've tried it both ways: bringing the ladderline to a coiled coax
balun at the window, with coax coming into the shack; and I've tried
bringing the ladderline directly into the shack.

I'm currently doing the latter -- the ladderline comes through the
wood-frame window opening (with a towel and toilet paper plugging up
the air gap), it then passes within 2 or 3 inches of a couple other
cables, and finally goes to the 4:1 balun on my Tmatch tuner. That
seems to work well. I think you have to just experiment and see what
works with each particular antenna.

Hi Jim,

I've seen reports of "better tuners" equipped with fans - take warning
that this would be a contradiction of claims and features.

What you fail to discuss is what is motivating you to make this
change? Do you perceive your tuner heating up? Does it fail to tune
your antenna? Are you having problems with Common Mode currents? Are
you bored with the current arrangement?

Hello
Well, what concerns me is that I may not have things working as well as they could be. I'm not having any problems and in fact this system works out quite well. I have read that a remote balun and coax will work, and it does, but going direct to a balanced tuner is better. But how much better? Is it worth the effort and expense? I'm satisfied that the LMR400 and Radio Works balun are as low loss as I can get for this kind of system, but I can never leave well enough alone if I think there is room for improvement.
Thanks

Dear Richard,

I finally created a test load that gives me the higher SWR that I
wanted.
It measures 7.0 - j2008 at 1.8 MHz. I placed that test load at the end
of a 150 foot piece of RG-59/U and measured the input impedance as
38.5 + j 151.6 at 1.8 MHz. The load SWR is 7901 and the input SWR is
10.18.

Solution of the transmission line equations for this particular load
and with coax characteristics of 73 ohms, VF = .646 and an attenuation
of 0.57 dB per 100 feet gives an input impedance of 38.67 + j 149,
which is a very good match to the measured value.

Losses are calculated using the same two methods as reported in my
previous posting, as follows:
1) ITT Reference Data for Radio Engineers, 5th Edition, pages 22-8 and
22-9.

2) The ARRL Antenna Book, 17 th Edition, page 24-9.

Matched line losses = 0.855 dB
Additional losses = 28.087 dB
Total losses = 28.942 dB

I am satisfied that the methods of calculating losses as described in
the two references are in agreement and are valid.

I am also reasonably satisfied that the 1 dB steps that are printed on
Smith Charts as the means of determining matched line losses are
valid, as are the nomograms provided in the ITT Handbook, pages 22-7
and 22-8, above.

Jim,
The differences between the two 'ways' can be fairly large. But, on the whole, I honestly doubt if you would 'see' any difference in performance. Running balanced lines near 'stuff' isn't as big a 'problem' as most people think. If you can stay away from things, fine. If not, then try to stay as far away as possible, and keep the proximity of the balanced line to other things 'symetrical' (if that makes sence), both conductors an equal distance from the other stuff.
'Doc

PS - If the idea is to try something different or new, have at it!

Jim,

Well, let me say this...

I've run window line for years, and will be switching to open wire line, in part, next year. In a test that I did about 7 years ago, I ran a 1 ft section of window line across a metal flourescent light fixture, laying right on it. I could measure no change in SWR and no change in signal strengths using a 40 m horizontal loop on 40 m. I'd recommend running a test if possible and see if it makes a difference.

Right now, I run an 80 m loop and run window line all the way to the tuner in the shack. Only metal is about a foot away, water pipes and heating ducts that parallel the feedline for about 25 feet. It works so if there is a problem, it might not be severe and I'm willing to live with it, hi.

73s,

Evan

Hi Jim,

Probably not enough for you to notice.

>Is it worth the effort and expense?

Worth is subjective, even if you feel good about, but discern no
evidence of improvement in performance, that may be sufficient.

>I'm satisfied
>that the LMR400 and Radio Works balun are as low loss as I can get for
>this kind of system, but I can never leave well enough alone if I think
>there is room for improvement.

As Doc suggests, goferit. Bob's advice is not uncommon either,
although absorbent material could get damp and affect local line
performance. The question then becomes one of our academic knot
twisters in that would it matter. Myself, I see a potential short
across the line and tender nearby to support combustion or smoldering.

To solve my 15X15 inch basement window problem, I replaced the plate
glass with Plexiglas and drilled holes with abandon. This replacement
was not without taking so long a time that my buddy lost his patience:
"Just bust that $5 worth of glass out!" Instead, I had to do this by
carefully removing the petrified putty all around - and cracked the
pane in the last nip. Care and precision is not always worth the
effort.

I considered a remote tuner and did in fact use the RT-11 for a couple
of years. It worked, but it was a bit troublesome. What I am doing
now is far better.
One of the things I have learned about autotuners is that they all seem
to have a higher insertion loss than a good manual tuner. Probably
due to the toroids, fixed caps, and relays they use. Good airwound
coils and variable caps are less lossy. So using an autotuner may be
convenient, but I have seen insertion loss figures as high as 65%
under some mismatch conditions!..
I can live with my current system, and it works just great. But since
I am in the market for a new tuner, I just wanted to know if I should
go T match or balanced, as I originally stated.
Thanks for all the feedback!
Jim

Hi Bob,

Congratulations are in order for your effort at the bench, regardless of outcome.

Congratulations are in order for your chain of reasoning, your attention to detail, and the obvious refinement of technique that is now agreeing not only with references, but is also consistent from one test to the next.

I still see some aberration in the data when you have to drive the cable Z to 73 Ohms to make the formulas work. It shows that the generality of the references is good, but with the instance of your data is a forced conclusion. I don't find that particularly upsetting as the accumulation of error could easily account for some of the differences.

You might want to revisit some of Bart's offerings in this thread; especially his discussion of the effect of Low-R loads as a source of Hi-Z, Hi-SWR.

The key to using balanced line is to know what impedance you are dealing with looking into the feedline. If it's too high, baluns don't work. If it's too low, tuners don't work. You can always measure the impedance but I have found that EZNEC gives a close enough approximation to the feedpoint impedance that you don't really need to measure it. Some of the principles are explained on my web page under "No-Tuner All-HF-Band-Antenna".

Who was it who published loss data based on laying the ladder-line
on a wooden deck and/or squirting a wetting agent on it? Did you
use a wetting agent?

You missed my point, I think. The counterpoise is the (poor) metal of
the radio and of the user's hand. Any connector/adapter will be coaxial
and probably low loss, but the counterpoise stays put. The feedpoint
rises but the "ground" plane does not. For an SMA adapter, it might not
be enough to hear a difference, but the radiated signal will be worse
when using such an adapter.

73,
Dave

Hi Bob,

You are, in the expression common here in the NW, whipsawing me with your changes in cable type. I failed to catch that in your post.

Given you are using 73 Ohm line, your results are very remarkable. I'm glad you've gone the distance. This group, however, exhibits a very odd ethic that I would call the reverse Little Red Hen story.

Through more than 150 postings they all want to offer advice on how to cut the grain; they will tell you where to mill it into flour; they will offer you recipes on what to bake; but none seem to be around to praise the chef or the cake.

I'd say "may be worse" rather than "will be worse". In some cases, it
may be better.

From what I've seen (and measured) the actual impedances,
"counterpoise" effectiveness, etc. of HT antenna setups vary all over
the map, and change constantly depending on a whole bunch of
factors... how you grip the HT, whether you happen to be wearing a
glove, how you angle the HT near your head (antenna-loading effects
from the head can make SWR change dramatically), and probably whether
you're sweating or not.

A typical HT case is almost certainly _not_ serving as a tuned
counterpoise at 2 meters, nor is your arm and body.

Adding a centimeter or three of SMA-to-BNC connector to the length of
the "counterpoise" may have some small effect in some cases, but I
believe that [1] it's as likely to work for you as against you, and
[2] it's probably less than the sorts of impedance variations which a
typical HT has to face every day as it's moved around the user's head
during transmission.

Dear Richard,

Well, I only came here to share, so I'm not the least disappointed -
as some say, the pleasure is in the doing!

You might have asked why I changed coax.

I didn't feel that it would be as dramatic with only 17.5 ft of line.
So, I went to the barn and looked for the biggest, cleanest roll of
coax hanging on the wall, and that was it - Hi!

Not to mention the fact that the reason you're adding the adapter is most likely because you are putting a better antenna on the HT. I doubt what you *might* lose by moving the feedpoint away from the "counterpoise" is not as much as you gain by changing the antenna; otherwise, why bother? At higher frequencies this may not be the case, but probably not within the realm of a dual-band HT.

I've been using the Gulyas adapter for years now. I use it primarily for attaching a Smiley 270 telescopic whip to my VX-5, since that antenna works very well configured as a 5/8-wave on 70cm. The relative gain in performance over the stock antenna is quite noticeable, so in that case, the adapter causes no problems. The fit and appearance of the adapter on that rig is great, too!

Hi Bob,

I didn't ask why because it was evident from the drama of results. May as well force the numbers to expose the theory. I tried that with my own thread when you started this one - it n'er came out as well as yours. However, your confirmation of the loss does support my thesis, even if my thread did not.

So what we're saying is that if it rains really hard (horizontal rain) and the rain happens to contain detergent, then that experimental result is valid! 8^)

I've had a ladder line fed antenna up for a couple years, and noted no difference between rainy and dry operation.

No, I didn't use a wetting agent other than Oregon rain (which was not squirted, but allowed to fall naturally from the sky). And your recollection of a line "laying" [sic] on a wooden deck might be because my line was supported above my wooden deck (several feet above the ground) by TV standoff insulators. Interesting how we remember what we want to, rather than what we actually read, isn't it?

Perhaps you should go back and read my posting. If you can't find it with a groups.google.com search, let me know and I'll post the date and subject title. Or, if you have back issues of QST, see Technical Correspondence in the February 1982 issue.

In the 22 years since publishing the test results, I haven't seen any objective and quantitative test results which contradict my findings.

Tell me, specifically, in which cases that my info would not be true. I made some measurements before I posted. Did you?

I was just saying that extending the feedpoint / current node, as was suggested, will lower the radiated power. I measured field strength measurements and then posted my results.

I still feel that the more aluminum in the sky, the better. Even if there is some loss in adapters... mmmm.... bigger antennas, happier hams.

Foundation license? Which is that????

Simon, good luck to you, and you should spend more time on the air than
you spend here. Get away from this web site - the rec.radio.amateur.*
newsgroups are mostly counter-productive. You will find people here
who, well, don't get on the air (I don't know how else to say it).

You should go work CW, work voice, spend some time on SSTV, and then on
PSK, and try some of the funky digital modes, and of course, do some
SSB, but make it so much fun that you can't even explain to your friends
why you spend every weekend doing it.

You will see -- it's the best hobby you have ever picked.

Take care, and all the best, and 73

Dave

This raving looney & class nerd hiked uphill both ways in a raging
blizzard to the Old Customhouse in Philly and passed the 5wpm Novice
thing 1953. Follwed shortly by the same trek for the 13wpm test for the
General. Thought I had it made for life and that I'd seen the last of
those squinty-eyed FCC examiners. But, nah, they reshuffled the deck
and "invited me back" in 1968 to take the 20wpm Extra. Figgered that
since we were getting snowed in I also took/passed the Second
Radiotelegraph to kill some time . .

. . . (so there) . . ?

The N7WS experiment was accomplished by coating the line with a wetting agent.

The wire was suspended horizontally, 12 feet of it.

The author notes that it was "difficult to maintain uniform wetness" during the time it took to run the experiment. This would mean that he likely pooled water on the line.

And finally, I performed a little experiment. I have the ladder line from that antenna that was up for 2 years. Application of some water showed that it would bead up very nicely.

I just don't think the test conditions are very realistic. But it does tell me not to wash my ladder line with soap and water! ;^)

Golly let me take exception Dave

The newsgroups - particularly this one is a great Amateur Radio asset --
many knowledgeable antenna gurus here.
Many technical questions and answers are fielded on the NG's every day.

Yes NGs are free and open forums -- so you will find many junk posts, but
weed thru them and there is really some good stuff.

As for being on the air -- anyone on HF will know that "A foundation
License" has been issued in the UK since January 2002
See URL:
http://www.rsgb.org/beginners/licences.htm

Many many folks on the NGs are on the air frequently -- see
rec.radio.amateur.dx or the digital or satellite groups

Anyway congratulations are in order for John in Cornwell.

Dave gave you some great ideas for modes of operation and I agree "You will
see -- it's the best hobby you have ever picked."

Welcome to Ham Radio

73, Happy Holidays, and enjoy the many facets of Amateur Radio

The way I tune my antenna system is by varying the length of the
ladder-line.
I have never seen rain make more than a two foot change necessary and the
SWR only ever changed by about 0.2. Two feet of feedline on 40m is not much
of a change in impedance and neither is an SWR change from 1.8:1 to 1.6:1.
Of course, I am savvy enough not to have a horizontal run of ladder-line out
in the rain. :-)

A few themes have shown up on this thread that seem to reinforce some misconceptions about antennas. They might not have been meant that way, but I think it's a good idea to clarify them in case a casual reader might drop by and be misled.

The first one is about where the "transmission line" ends and where the "antenna" starts. The antenna starts at the point where the two current carrying conductors move far enough apart for significant radiation to take place. By way of illustration, let's take the example of a simple vertical mounted on a perfect ground plane. We'll feed it at the bottom via a piece of coax. It doesn't matter where the coax is, above or below the ground plane. Inside the coax, there's current on the outside of the inner conductor, and an equal amount, flowing the opposite direction, on the inside of the outer conductor. The fields from these two currents cancel everywhere outside the coax, so it doesn't radiate.

At the point where the coax connects to the antenna, the current from the inner conductor flows up the antenna. The (equal) current from the inside of the shield flows over the ground plane, spreading out from the point where the shield connects to the ground plane. The currents are now physically separated, so their fields no longer cancel, and net radiation can result.

An important feature of this setup is the effect of the current flowing along the ground plane. For every bit of current flowing outward in one direction, there's an equal bit flowing outward in exactly the other direction. The fields from these two bits of current cancel at right angles to the directions of flow. When you look at all the bits of current, you find that the net field from the whole amount of current is zero. So the current on the ground plane doesn't result in any radiation. (By contrast, the current on the antenna wire doesn't have any cancelling current, so it radiates.) A conductor which carries current but doesn't radiate (significantly) is often called a "counterpoise". Misuse of this term is another problem with some of the postings, and I'll address it in a minute. The important thing to remember is that a "counterpoise" doesn't radiate significantly. If it does, it's not a "counterpoise" but a part of the antenna.

What happens if we put a piece of pipe around the bottom, say, 1/4 of the antenna, weld it to the ground plane, and connect the coax shield to its inside? Now the pipe is an extension of the transmission line. The portion of the antenna inside the pipe is the center conductor, and the pipe is the shield. So the portion of the antenna inside the pipe can't really be called an "antenna" any more, since it doesn't radiate.

The current on the inside of the pipe reaching the top of the pipe flows over the edge and down the outside to the ground plane. Here's a very important point: *This current radiates just like the current on the antenna wire*. What we have now is a lopsided dipole. The antenna wire protruding from the top of the pipe is one side of the dipole, and the outside of the pipe is the other. The "feedpoint" is where the wire sticks out of the pipe. Once the current along the outside of the pipe hits the ground plane, it spreads as before. The current on the outside of the pipe radiates, the current on the ground plane doesn't.

A statement was made about a situation sort of like this "shielding" the "high current" part of the antenna. This isn't what happens at all. What happens is that the portion of the original antenna wire inside the pipe is no longer an antenna at all, but part of a transmission line. The current on it isn't the same as before the pipe was put there. The radiating antenna is now the portion sticking out of the pipe, and the current at its bottom, all other things being equal, will now be greater than before the pipe was added. No signal or power is lost due to "shielding". All you've done is shortened the antenna a bit, just as though you'd cut a bit off the top.

Now let's remove the pipe and bend the ground plane downward into a cone, with the antenna sticking out of the cone's apex. Here we'll find that the current flowing on the ground plane does indeed radiate. There's no net radiation straight up, but it radiates horizontally and in all other directions. The ground plane is no longer a "counterpoise", but simply a conically-shaped dipole half. If the ground plane radius was about the same as the "antenna" length, and the ground plane is bent downward at a reasonably sharp angle, the radiation from the conical ground plane will be about the same as the radiation from the "antenna". Calling it a "counterpoise" doesn't give it magical properties so we can ignore it -- it's every bit as much a part of the antenna as the "antenna".

Finally, consider an HT. Here, one half of the antenna is the rubber ducky or other "antenna". If you put a sleeve over part of the outside of it, the real radiating top part of the antenna is the part sticking out of the sleeve. The other half of the antenna -- NOT a "counterpoise", but a real part of the antenna of at least equal importance to the intended part -- is the outside of the sleeve, and the outside of the HT, your hand, and your body. Whatever current flows up into your "antenna" also flows along the other half -- that is, along the HT and your body -- and radiates.

# 3236. New version 4nec2 freeware antenna optimizer

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-07 12:55:32 UTC
From: 4nec2@gmx.net
Message-ID: <ee90361b.0412070455.4eee8627@posting.google.com>
Source record: 85633

Hello...,

for those interested, just released the latest 5.4.1 new version for the freeware 4nec2 antenna visualizer and optimizer.
(see http://www.si-list.org/swindex2.html and look for 4nec2)

With this the below new features are now availble for use:

- Batch processing for automatic testing and calculation of multiple (4)Nec2 files.
- Extensive Nec-2 segment- en geometry validation, such as: Intersecting volumes, Short/thick wires at sharp angle, Unequal segmentation for parallel wires, Too low hight, Large radius or length changes at junctions, etc.
- Screen grabber for easy cut/paste and print or save parts of the screen/window/form.
- Automatic convergence-testing function with line-chart result display.
- Enhanced variable-sweeper function for more easy use.
- Automatic generation of L, Pi and T matching-networks (low- and high-pass)
- Plot 2D and 3D graphs/charts using gnuplot freeware package
- Show Circular Polarization components for the far-field.
- Switchable Eznec- or traditional-style current display.
- Use of Insulated-Wires and 'LC-trap' loading-types.
- Updated build.exe to avoid unconnected or overlapping wires

For those not (yet) familiar with the 4nec2 package below some of the other 4nec2 'highlights':

- Drawing style geometry editor to assist the starting antenne modeller.
- Graphical 3D visualization of Far- and Near-field data and antenna strutures
- Line-chart visualization for freq-sweep Gain, F/B, F/R, SWR and impedance data.
- Full Nec-2 command support, including GX, GM, GR, GA, GH and surface patches.
- Support for inclusion of surface-wave in far-field data.
- Variable substitution included for complete Nec-2 command set.
- Sophisticated real-time 3D viewer showing real wire-radius for modern-computers
- Capable of using the max of 2Gb of windows on-board memory (appr. 11000 segs)
- Interactive Smith chart visualization for freq-sweeps
- AO-style gradient/hill-climbing optimizer included.

- Genetic Algorithms based optimizer included.
- Automatic variable sweeper included.
- Integrated Sommerfeld ground calculations.
- Running on all systems from early Windows-95 to latest Windows-XP
- Context sensitive Help-file.
- Completely free.

Arie.

Not to diminish anyone's achievements, but that is the way to do things.
Take as many tests as you can, at one time. Keep on taking them until
you fail one. Then go back home and study some more.

As long as we are beating our chests, several years ago I walked in to
the testing station and took the Technician test, General test, and
13 WPM test in one sitting. Aced them all. Then, 6 months later, I did
the Advanced test, Extra test, and the 20 WPM in one sitting. Again,
acing them all.

But congratulations to John in Cornwall UK. We will be waiting to hear
you on the bands. Not only are we NUTS, we are MIXED NUTS.

The *magnitudes* and *phases* of Vfor and Vref are affected by Zs as
described by Chipman. But I don't find anything in Chipman's book to
indicate that the *ratio* of Vmax to Vmin (VSWR) is affected by Zs.

Perusing all the references to VSWR in Chipman's book, you will find
that the source is not mentioned at all. Only the load reflection
coefficient
and the transmission line characteristics are needed to calculate VSWR.

Jim,
with respect to keeping the system all balanced and running the balanced line through portals along with metal objects,
you can simply make a length of shielded balanced line using two pieces of coax with the braids connected at each end and connected to shack ground on the inside end. It becomes a shielded balanced line of twice the coax Zo and can be directly inserted into the transmission path with no problems.

Check out "Some Aspects of Series and Parallel Coaxial Cable Assemblies" at Cebik's site, in particular the "Series-Connected Coax" section

http://www.cebik.com/spcoax.html

John
I read that link with great interest. Some years back I saw an article where twinlead was constructed out of coaxial cable for the purpose of running it through environments that would be bad news for normal twinlead. I thought it was rather stupid because the loss on such a line would defeat the whole purpose of using twinlead. However, for my purposes where I just need a couple of feet or less to be in close contact with other cableing, this might work. The question is, why then are remote baluns promoted as the solution to this common problem? And, is the coax twinlead and a balnaced tuner a better choice than a short lenght of very low loss coax, a good current balun, and a T match?
I am not trying to be difficult, I just want to set this up as efficinetly as possible. This might actually be the key! I just need to know if I should go with a short section of coaxial twinlead and a balanced tuner...or leave well enough alone.

That is a 3% change. Shorter. Check the VSWR to see what BW you are
getting. You maybe able to cut the driven element slightly, or just change
the postion of the gamma match. Since the rest of the antenna can't change
the element positions the antenna is stuck at 432 with the BW it has, which
may include 445. 3% is a small change, within mechanical tolerances, and the
gamma match may define where the best VSWR is.

Gus wrote:
"These bolts are 12 inches in length 9 inches in the concrete and 3 inches extending for the tower base. If I guy the bottom section and use a fairly light antenna (HF quad) will I be okay?"

I am not a civil engineer, but I have erected countless towers. My degree is in electrical engineering.

Once the guys are satisfactorily in place, you have no need for nuts on the tower base bolts. There is no overturning force on the tower. It is resisted by the guywires. If you have a guywire accoident, you may be glad you have nuts on the tower base bolts. It`s happened to me and though the tower bent over like a fishing rod with a big catch, no harm was done. The manufacturer was in PA, Stainless Manufacturing, and the towers were ordinary tubular steel. Sawing open a tube showed a pristine interior. No rust.

Best regards, Richard Harrison, KB5WZI

|>
|>
|> Who was it who published loss data based on laying the ladder-line
|> on a wooden deck and/or squirting a wetting agent on it? Did you
|> use a wetting agent?
|
| The N7WS experiment was accomplished by coating the line with a wetting
|agent.

No, the line wasn't "coated" with a wetting agent, a drop of
Microclean was added to a spray bottle of deionized water.

|
| The wire was suspended horizontally, 12 feet of it.
|
| The author notes that it was "difficult to maintain uniform wetness"
|during the time it took to run the experiment. This would mean that he
|likely pooled water on the line.

No, I never said that either. For greater accuracy, 201
point-by-point measurements were made over the frequency range. This
takes some time, during which the moisture layer moved around (i.e.
was not uniform). This had the effect of corrupting the data
somewhat.

|
| And finally, I performed a little experiment. I have the ladder line
|from that antenna that was up for 2 years. Application of some water
|showed that it would bead up very nicely.

Bring your line out here to Arizona and leave it in the sun for two
years and re-run your experiment.

No, on second thought, don't come out here. There are too damn many
people moving here already and polluting the air with plasticizers.

At least Cecil left and went back to Texas.

|
| I just don't think the test conditions are very realistic. But it does
|tell me not to wash my ladder line with soap and water! ;^)

I stated, "The results of this are probably worse case and not
something that would necessarily be encountered in a typical
installation."

Also, if you would look at my "update" on my web site, you would see
the following:

"As an aside, I regret including so much about the wet condition. I
tried to make it clear that this was really worst case and not
something that would be seen in practice, but there has been so much
negative commentary about it, that it detracts from the point I was
trying to make."

I'll add you and Cecil to my list.

> and the transmission line characteristics are needed to calculate VSWR.

==========

Cecil, the trouble with 'bibles' is that they are so easily misquoted.
It's always better to rely only on your 'own' knowledge.

Only the MAGNITUDE of the reflection coefficient is needed to calculate SWR.
The phase angle is superfluous.

Nothing else whatever need be known about the line. Not even Zo, the
terminating impedance, and certainly not the generator impedance.

Conversely, the SWR will tell you virtually nothing about what's going on on
the line until you include and add to it what you already know anyway. You
can't even work back to find the reflection coefficint because of the loss
of the angle information.

The reflection coefficient is of no use to anybody without its angle,
except, of course to calculate the SWR.

Abolish SWR meters!
---
Reg.

HI Frank,

Commonly 1.5 to 3 Ohms resistive transformed to 35 Ohms to 70 Ohms at the Connector.

>or even a tube amplifier?

Much greater variation here, X KOhms resistive transformed to 50 Ohms at the connector.

Such are ballpark figures, as an average over a full cycle, at rated power, for Class AB operation in a Push-Pull configuration. This typically results in an efficiency on the order of 40% to 60%.

The nut of the matter about "Source Z matters" is that if your source were at either of those untransformed Zs that are native to transistors or tubes, then almost all their power would be reflected back into them at the antenna connector's connection to a 50 Ohm antenna system.

The argument of the matter about "Source Z matters" is that if your source were at either of those untransformed Zs that are native to transistors or tubes, then reflections from the load (once you got some power into line) would encounter this same massive mismatch and re-reflect. There is a naive argument here (all too common) that this is "exactly" what happens. My pointed observation to those statements is "why would anyone need a tuner then?"

The refinement of the matter about "Source Z matters" is that if your source were at either of those untransformed Zs that are native to transistors or tubes, then with any mismatch at the load you haven't got a clue what power is being applied OR reflected. This is called the Mismatch Uncertainty. It is another indicator of the failure of the argument mentioned in the previous paragraph.

The relevance of the matter about "Source Z matters" here is that the references that Bob used to measure and model line loss supports this thesis. It presents an opportunity to observe how a line would suffer additional loss through being mismatched at both ends. In this regard, it would be due to the fictive argument for Source Z being very much lower or very much higher than 50 Ohms (in other words, lacking the transform circuitry commonly found in commercial gear). When the loss is not observed, the fiction is shown.

Hi Richard,

With solid state power amplifier design; the criteria was always that you must present an impedance, to the output devices, such that the desired output power is delivered to the load (while not exceeding device dissipation). Any attempt to optimally match the load to the source impedance will result in over-dissipation, and probable destruction of the source device -- probably by excess collector/drain current. If you remember, Motorola used to publish Smith charts of the output impedance for their power amplifier devices. Talking to one of Motorola's design engineers; I asked "How do you derive these Charts". His answer was; "We use a matching network and adjust it for the required output power, then measure the input impedance of the network. The complex conjugate of this impedance is then defined as the source Z". The fact is these data are not the actual source Z of the device, but are probably considerable higher. I don't remember anybody actually trying to measure the large signal S parameters of solid state devices.

I seem to remember that tube amplifiers were designed based on the source impedance calculated as 2Vp/Ip, (Where Vp is the plate voltage, and Ip the plate current), and have no idea how, or if, it relates to the actual source Z of the device. Anyway, I am not convinced that source Z is important. Where I think some confusion may have come from is Hewlett Packard's 12 term error correction analysis derived for vector network analyzers. Here source Z is important because measurements are made in both directions.

I have some conceptual problems with standing waves, and reflected power, although I know that the solution to the wave equation shows a forward and reverse traveling wave. Both with uniform plane waves, and in wire transmission lines. Transmission lines can also be analyzed as a simple passive network without regard to "Reflected power".

I am sure you will rip my comments to shreds, that's ok, as I may learn something.

Thanks for that info..I would consider that as "bad"..Hi.
But the Palstar reviews that I have read all seem to be quite
favorable.
I am now using an old Daiwa tuner that does a real nice job, but it is
old and uses small 365 mmf broadcast type variables, a dainty looking
coil, and cheap push switches for antenna selection. The cross needle
metering seems to be OK.
I just want to upgrade to something built a bit better, and I am not
fond of Mighty Fine Junk ( no offense intended ), even if they are the
most popular in the world.
I probably will go for a Palstar, but I can't decide on a T match model
or the balanced tuner.
Thanks for the reply.
Jim

Yes, I remember.

For those that are interested, Danny lives amongst the Redwoods on the
N. California coast and he sent me a length of window line that he had
taken down that was covered in moss.

I had hoped to get set up to measure it but the 10% RH in Tucson
conspired to kill the stuff.

Nevertheless, I suspect that it was no longer a low-loss line but a
high-moss line instead.

> then are remote baluns promoted as the solution to this common problem?

Well, there's more than one way to skin a cat, a remote balun wouldn't be bad if it fed the balanced feedline of a resonant antenna which is used at its resonant frequency. But if you want to operate the antenna everywhere then you don't want a balun feeding the open wire, weather it be at the antenna or on the antenna side of a shack side antenna tuner.

Go to Cebiks index section, in particular the Transmission Lines, Impedance Coupling, and Construction section, - there's lots of reading there on antenna tuner matching issues including a great tutorial :^)
http://www.cebik.com/radio.html

> And, is the coax twinlead and a balnaced tuner a better choice than a
> short lenght of very low loss coax, a good current balun, and a T
> match?

Oh Yes. If you keep everthing balanced and then use a GOOD balanced antenna tuner things will work out fine.
Avoid any balanced tuner design that has a matching network followed by a ferrite core balun on the *antenna feedline* end.
These types of baluns are meant to be used close to their design inpedances, not when connected to a multiband antenna which is going to have wild variations in Z.

http://users.triconet.org/wesandlinda/ladder_line.pdf

Is my source.

The quoted text:

The reason for lower accuracy of we measurements is that it was
difficult to maintain uniform "wetness" during the several seconds it
took to make the measurements. Nevertheless, this lack of control is not
much different than the actual conditions a line might encounter in the

field.

end quote.

I'm assuming that you tried to maintain uniform wetness, hence the
judgment that it was difficult to do so.

For greater accuracy, 201

Gee Wes, I'm not trying to make a big argument with you! The experiment
was well conducted. But I do disagree with the initial assumptions. I
think wetting agent on a horizontally placed line is indeed worst case,
but it is a worst case that is not likely to ever happen in real life.
As you pretty much note.

And you are welcome to visit us here in beautiful Central PA any time

# 3267. Re: Open wire source? - Re Loss Due to Rain and Dirt

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-07 21:30:27 UTC
From: Irv Finkleman <finkirv@shaw.ca>
Message-ID: <41B62137.FA2A0B21@shaw.ca>
Source record: 85664

I once decided to try 300 ohm twinlead on my inverted Vee. I picked up
the cheapest stuff I could get from Radio Scrap and dropped it from the
vertex at about 50' down into the shack. It worked so well that it stayed
up for thirteen years.

I never cleaned it, and it went through all kinds of weather including
rain, freezing rain, snow, and at times was coated with hoarfrost. I never
noticed any degradation due to rain or snow.

I didn't do any measurements on it, and perhaps tweaked the tuner once
in a while, but in my opinion it was the best antenna I ever had (discounting
beams, mag loops, and verticals).

It went up in 83 and came down in 96 -- clean as a whistle, and was cut into
j-poles and other smaller antennas.

Anecdotal perhaps, for what it's worth...

Irv VE6BP

I still have a bit of it in my shop waiting for some future requirement.

Source record: 85665

Most people wouldn't notice if a few dB of loss come and go, unless it's very abrupt. (And even then, it might not be noticed except under unusual or very low-signal conditions.) Ionospheric conditions cause much greater changes. Unless we have a solid reference antenna for comparison, there's no way most of us would ever know if a few dB of loss was coming and going. And, most people wouldn't care anyway.

When we pigeonhole antennas into the binary categories of "works" and "doesn't work", there's a lot of room for slop in where the dividing line is drawn.

Thanks - I wasn't too worried about the SWR node, but rather the gain peak. I figured that I could shave off a millimeter or two (or three?) from each element to raise the frequency of maximum gain. Not having any yagi-modeling software, it wasn't clear to me what would happen. Maybe it's not worth the effort.

|> |tell me not to wash my ladder line with soap and water! ;^)

I guess I fail to understand what "realistic" conditions should apply. Should I have taken a $250K analyzer out to your back yard or Cecil's? [g]

The situation was thus:

I had a day job, trying to keep AMRAAM, TOW and Tomahawk missiles flying. If I and the equipment weren't otherwise tied up, I could make a few "personal" measurements.

I didn't measure only one sample, but five different lines, including the open wire control.

The measurements were made in a 16' x 20' shielded room with an 8' ceiling. This, the equipment placement and the need to access both ends of the lines, unfortunately limited the length of the samples and other factors dictated the frequency range that was usable.

The lines had to be taut, since the open wire line had no spacers other than at the ends.

Horizontal seemed logical since any other orientation brought the ends closer to the metal walls of the room or allowed the open-wire conductors to sag toward each other.

I started with no, zip, nada, zero "initial assumptions", other than the stated belief that hams tend to think that these lines are lossless in almost any application and that I could make decent measurements and find out. I had no ax to grind. I personally don't use window or open-wire lines, preferring Heliax and resonant antennas instead.

Wetting the lines was almost an afterthought. I remembered Roy's Technical Correspondence on the issue and other anecdotal reports and thought I would take a quick look. (With Roy's permission, I will put a .pdf of this on my site)

Hi Frank,

I've heard variations of this before, and other's admonitions that Motorola admitted to a huge specification mistake in the early 90s and had since mended their ways. When I asked for these updated references, I ended up quoting verbatim from those mended teachings, that, yes, Source Z has always been what was specified before (...1990s), it was the same then (1990s), and it is the same now (1990s...).

I've just returned from a nanotech seminar this afternoon whose subject was organic thin film transistors. Dr. Daniel Frisbie - Depts. of Chemical Engineering and Mat. Science - University of Minnesota, offered that this new generation of research confirmed that the Resistance of the transistor channel (similar to a MOSFET) easily dominated all other sources of impedance. They also tested for junction offsets (valence band - conduction band potentials) and found they were negligible. The electron mobility wasn't the hottest thing going (semiconducting carbon nanotubes easily dominate), but there were no surprises. One of the EEs in the crowd easily allowed the OTFTs showed no chemical/physical/electrical departures from expectations (except for his concern for Schottky bias).

The technique you describe above is called a transfer standard. Unless there is some mysterious shift in the space-time continuum to account for this operation being invalid, it fully and accurately describes the unit under test. Most arguments that lean on this indirect measure being suspect would have us counting electrons instead of using an Ammeter. Then we would argue about the counter and its incapability of being a direct measure, but simply another abstraction. Inevitably the arguments spiral down to the retort "you are not going to change my mind."

I am already in the middle of the science that does real electron counting, literally, where one can find what is called the Coulomb

barrier. For carbon nanotubes, things are so small that one electron in a "wire" cannot allow another in with it to share the conductor. Nothing like that is going on in our rigs.

I agree Roy. I'm the stick it up in the air and if I work lots of stations
and hear things most of the other local stations can't then I'm a happy camper.

I'll settle for all the space between 'works' and 'doesn't work' -- much
less stress and lots more fun. I guess thats why they say 'Ignorance is
Bliss' or 'What they don't know won't hurt them'

Hi Richard, thanks for your comments. My contacts with Motorola were in the late 80s, so does put it in the correct time frame, and does not surprise me. I know I thought of it as a not very elegant method. The particular device I was thinking of was a dual push-pull (could have been parallel) module designed for about 200 - 500 MHz, at about 50 W. As far as I am concerned Motorola has gone down hill since they used to produce those thick RF device data books. Not to mention 4DTV. During that same period everybody was using a technique known as "Load-pull" for power amplifier design. I was also involved, though not very deeply, in the design of 100 W to 1 kW HF solid state linear amps, where I was told the same story about not attempting to actually match the bipolar devices, but simply present an appropriate impedance to obtain the output power; otherwise the device parameters will be exceeded. I am far from an expert in the field of power amplifier design, but it would be interesting to know if high power transistors are now characterized by large signal S parameters. This may sound really dumb, but how about feeding 100 W back into a transistor amplifier, and measuring the return loss. It would at least give you the large signal magnitude of S22.

You are starting to loose me when it comes to semi-conductor physics, as it was not a field that I was especially interested in. I think the only journals that I may have read about "nanotubes" may have been Scientific American. I have also never had any experience with power FETs.

73,

Frank

Roy & group:

I have heard of holding a quarter-wavelength of wire next to the HT
while transmitting. This has been called a "tiger tail" and is supposed
to improve you radiated signal.
<http://adjunct.diodon349.com/Radio/ht_tiger_tails_and_other_good_info.htm>

Some attach this to the bnc at its base - others to the belt clip -
still others just hold it beside the radio as they transmit.

Do you think it might do any good?

Hi Frank,

There used to be an old, old song: "Yes dear you can go swimming, but
don't go near the water."

Even at DC, you cannot design to the capacity of a transistor, because
the combination of all capacities exceed the "safe operating area."
However, this does nothing to actually change any noted specification.

I've never seen ANY power amplifier for retail trade conjugately
matched to its Source Z. But then I have never seen ANY amplifier for
retail trade designed to be low noise, low distortion, high stability,
or any of the more common qualities that "could be" designed in, if it
weren't for cost and the perception of no particular boon to the
purchaser. Who needed low distortion when you could throw a cheap
filter on the output? Who need low noise when atmospherics dominated
such issues? Who needed stability when the monkey twisting the knob
would correct it as a form of entertainment? Safety margin? Add a
fan to the heatsink - $pecial option.

This was done decades ago - it is called an active load. I used to
calibrate them too. Guess what, it was specified and it met spec at
50 Ohms (and at least 100W).

A bunch of people in one of my area's hamclubs have built these...
they're the "fasten to the BNC base" variety.

Most of the peopple who made 'em, report significantly-improved
transmit range with their HTs.

One guy spends a fair bit of time up in San Francisco, and likes to
check into a net on the Stanford repeater. Without the tiger-tail on
its HT, he was able to get into the repeater reliably only by going
through some significant hassle (e.g. standing on a fire hydrant and
holding the radio just-so) to find an RF propagation path which
worked. He could not reach or hold the repeater while walking along,
pedestrian-mobile. With the tiger-tail in place, he reports that he
has no trouble getting into the repeater and holding it reliably while
just walking down the street.

The benefit seems roughly similar to switching from a short
rubber-duck antenna to a full quarter-wave "spaghetti noodle".

It's hard to make too many generalizations about HTs and their antennas, since the hand/body is such an important part of the system and it's so variable.

But HT antennas still have to follow the rules like everything else, so we can get something of an idea of what a "tiger tail" does by knowing the rules.

Remember that whatever current goes into the "antenna", an equal and opposite current (from the inside of the transmission line or connector) has to flow down over the rig, your hand, and body. (It comes out of the rig on the inside of the coax antenna connector shell.) Like any other current, this will split whenever it has more than one available path, and like any other current, the magnitude flowing each way is in inverse proportion to the impedance of that path. If a "tiger tail" is pretty close to resonance (not at all guaranteed by making it a quarter wavelength long, since it'll be influenced by nearby and touching objects), it'll represent a pretty low impedance. If it does, a good share of the total current will flow onto the "tiger tail" and less on you. It's likely, but not guaranteed, that the tiger tail's radiation will reinforce the "antenna"'s radiation better than the radiation from your body would -- although in some cases the body does act somewhat as a reflector. Also, the body is a lossy conductor, and I think that at 2 meters that would be true even considering the large area. So any current diverted to the relatively low loss "tiger tail" will at least contribute to radiation in some direction, rather than producing heat.

The best portable antenna I've found for an HT is a base-matched half wave whip like the AEA "Hot Rod" or MFJ's copy of it, although it's unwieldy. The great advantage of this antenna is that the base current is very low, so the current flowing on your body is also very low and the antenna does most of the radiating.

It's terribly difficult to do really good antenna measurements, but I was impressed with the effort put forth by Pierpoint and Brummer (KF4OW and W4RTZ) in doing their best to make objective measurements of some common HT antennas. Their results are certainly good enough to draw some general conclusions. You can see them in "An Investigation of 2-Meter HT Antenna Performance" in the _ARRL Antenna Compendium_, Vol. 4 (p. 198). Unfortunately, a "tiger tail" wasn't among their tested configurations.

Bob & group -

I downloaded it and created a folder for it and unzipped it to that folder. Then I ran setup.exe which got to this point:
"Setup cannot continue because some system files are out of date on your system. Click OK if you would like setup to update these files for you now."

I clicked on "OK"

Next setup gives me this message:
"Do you want to restart windows now? If you chose 'No' you will not be able to run setup again until after the system is rebooted."

I choose "yes"

Setup message: "copying files. Please stand by.

and eventually:

"Processing MSVBVM60.DLL (7 or 7)

and the system reboots.

When I examine the folder containing the unzipped files, nothing has changed. If I run setup again I get the exact same messages as above. It seems I'm stuck in a loop.

I'm running Windows ME and my copy of MSVBVM60.DLL is in c:\windows\system with a mod date of 2/23/04.

What am I doing wrong?

The problem is that the "works" threshold is different for every person and every situation. A lot of people seem to believe that what "works" for one person and situation will "work" for them for their own particular situation. Simply accepting that is much easier than thinking, but then we've all been conditioned to be satisfied with solutions to complex problems in the form of 30 second sound bites.

What I try to do is explain the relative merits of one approach or another, in a quantitative way when possible, so those one or two people out there willing to spend a few minutes of thought can decide for themselves how to best trade things off -- whether one method or another is more likely to "work" for them. I know this isn't a popular approach in today's instant-gratification world -- thanks to those sound bites, any response that isn't grossly oversimplistic has forever been dubbed "waffling".

I had heard that also. For a typical VHF/UHF device, the manufacturer's application engineers use an infinitely adjustable stub tuner to explore the whole range of possible load impedances presented TO the device.

As well as measuring output power, the application engineer also has to think about maximum voltage and current ratings, chip and bond wire temperatures, and also IMD performance if the device is going to be specified for linear operation.

The application engineer adjusts the load impedance to give the optimum balance of all these factors, at a series of test frequencies. No problems whatever about that.

The only technical issue is the *assumption* that the conjugate of the load impedance is equal to the output impedance of the device. Most manufacturers now tend to avoid that assumption, because it is a totally unnecessary distraction for the transmitter designer who has to use the device.

All the designer has to do is create an output network that presents the manufacturer's recommended load impedance TO the device. This network replicates the impedance transformation of the original stub tuner setup, but uses mostly fixed components for obvious practical reasons.

Apart from a very few special applications where reverse termination is important to avoid ghosting and similar effects, the transmitter designer doesn't have to think about the device's output impedance at all.

Maximum power transfer with conjugate matching is undisputed. The problem with semi-conductor devices is that you cannot necessarily conjugate match because the device operating parameters may be exceeded.

Exactly.

Richard's assertion relies on at least three things being true:

1. That maximum power is being transferred - for most states of
transmitter tuning, loading and drive levels, that is obviously *not*
true.

2. That the transmitter can be accurately represented as a
"constant-voltage generator of internal impedance Zg", i.e. as a
Thevenin source.

3. That as part of #2, Zg is a constant.

With all due respect to Richard - and above all, respect to Walt - it is
a tall order to prove that all three of those requirements for conjugate
matching are being met. I believe they can only be exactly met under a

few very special sets of operating conditions.

But it then follows that, for all *other* operating conditions, the complete end-to-end conjugate matching referred to by King et al does *not* exist.

It seems everybody is in agreement with the fact that you cannot match a power source to the load. As Ian states: "nobody cares, what the device output parameters are, only that it is capable of delivering the required power to a desired load". This still leaves the question unanswered as to "What is the actual device S22"? I have read that "With HF linear devices the large signal S parameters are close enough to the small signal values". For non-linear devices load-pull techniques are used. I have never seen high power transistors characterized with S parameters, but have not worked with such designs for a number of years, so am probably out of touch. A tentative search of the web did not find any info. It seems TRW and Motorola are pretty much out of the power semi-conductor industry.

I am tempted to synthesize a transmission line based on the per-unit length parameters, and see how the load power varies as a function of source Z. It seems to me the only important factor is the applied voltage. The input impedance is only a complex number. The transmission line could be considered a "Singly terminated network", the synthesis of which is trivial, and performance independent of source Z. I have trouble with the concept of "Reflection"; how can charges (electrons) flow in both directions simultaneously. Charge flow results from the E field within the conductor.

73,

Frank

wrote:

|Hi Richard,
|
|With solid state power amplifier design; the criteria was always that you
|must present an impedance, to the output devices, such that the desired
|output power is delivered to the load (while not exceeding device
|dissipation). Any attempt to optimally match the load to the source
|impedance will result in over-dissipation, and probable destruction of the
|source device -- probably by excess collector/drain current. If you
|remember, Motorola used to publish Smith charts of the output impedance for
|their power amplifier devices. Talking to one of Motorola's design
|engineers; I asked "How do you derive these Charts". His answer was; "We
|use a matching network and adjust it for the required output power, then
|measure the input impedance of the network. The complex conjugate of this
|impedance is then defined as the source Z". The fact is these data are not
|the actual source Z of the device, but are probably considerable higher.

The data were useful as presented. When using a Smith chart for
matching network design, the published data could be used as the
"starting point" for the network and the rotations were made toward
the load; the opposite from the usual case of matching a load to a 50
ohm source.

This method was really an early example of load pull characterization.
Maury Microwave app. note 5C-041 is one reference for this. Another
is "A New Load Pull Measurement Technique Eases GaAs
Characterization", Microwave Journal, Nov, 1980, pp. 63-67.

|I don't remember anybody actually trying to measure the large signal S
|parameters of solid state devices.

|I seem to remember that tube amplifiers were designed based on the source
|impedance calculated as 2Vp/Ip, (Where Vp is the plate voltage, and Ip the
|plate current), and have no idea how, or if, it relates to the actual source
|Z of the device.
|Anyway, I am not convinced that source Z is important.
|Where I think some confusion may have come from is Hewlett Packard's 12 term
|error correction analysis derived for vector network analyzers. Here source
|Z is important because measurements are made in both directions.

It's not the error correction that is confusing. The error correction
simply removes systematic errors from the measurement(s). The
parameters usually measured when 12-term correction is called for are
the small-signal S-parameters. If I understand you correctly, "source

Z" is actually the output reflection coefficient (s22), the signal exiting port 2 due to an input to port 2.

The amplifier output reflection coefficient can be very important, even in high power amplifiers, when non-dissipative filters are used for harmonic or spurious rejection. Such filters are commonly specified and measured in 50 ohm systems and function by reflecting, not dissipating, the out-of-band energy. When driven by other than a 50 ohm source the rejection will be other than what is measured in a matched condition.

Have you ever stood on a cliff overlooking the ocean and seen
ocean waves rolling in and smaller waves rolling back out? The
smaller waves rolling back out to sea are reflections of the
large waves incident upon the shore. The small outflowing wave
meets a large incoming wave and seems to disappear, only to emerge
on the ocean side of the large wave with its identity still intact.

If ocean waves can flow both directions using the same H2O carriers,
why would anyone have difficulty in accepting EM waves flowing
in both directions using the same electron carriers? The energy in
the ocean waves travels much faster than the water molecules. The
energy in an EM wave travels much faster than the electrons.

Ever played with a long rope fastened at one end? You can send a
wave down the rope and receive a reflected wave. If you time it
just right, you can have a forward wave and a reflected wave
meet in the middle of the rope and be unaffected by each other
as long as things remain linear. A forward EM wave has no effect
on a reflected EM wave and vice versa as long as things remain
linear.

Hi,

Using a /MM station with a Iridium handheld, its data kit and a microwave dish antenna lays on the deck, is there a way to receive weather message in the same way as HF fax i(n USB with a computer) but now in those microwaves frequencies ?
What is the required material or downverter to receive weather msg (is possible) ?

I know what to use for meteosat and other "low frequencies" transmissions, but nothing or quasi about Iridium.
Subsidiary question : is there a way to receive weather message using Inmarsat network ? What solution 'd be the best (easiest or cheapest)

Thanks in advance

Hi Frank,

If we return this from the ethereal landscape of sub meter
wavelengths, back to the point of Bob's measurements at HF, and lately
the MF; then matching and issues of the final are trivial with a
million examples in the market today.

I know you would probably like to get to the nut of this, and it will
return you to Motorola's AN1526. This work contains much of the
language offered by correspondents here (in times past), but through
the rather gauzy filter of their memory. Usually they couch the
disassociation of Source Z to a transistor through poor context (in
other words, not reading the entire subject, but just a phrase).

There is the presumption these posters embrace:
"They consider the best match is achieved by a simultaneous
conjugate match of the input and output. However, power amplifiers
provide higher power gain and better efficiency at the rated
output power if the output is purposely mismatched. An added
benefit of doing this is potentially unstable devices, conjugately
matched, can be operated stably under these more optimum
mismatched conditions."
This is the usual mistake of misattribution between the distinctions
of a Conjugate Match, and a Z Match. However, you will note that
here, and elsewhere in the reference, that no one denies the Source
has a Z, and it is significant (all within values I've offered) and
that it is still closely held to the expected load (later I will show
exactly held).

Another dismissal offered by posters is the supposed invalidity or
inaccuracy of the load-pull method (which I find curious after having
calibrated active loads suited for just this purpose). I will turn
again to this same reference:
"Although the technique has been known for some time, the
widespread availability of desktop computers and automatic tuning
systems is just now making this method more attractive,
particularly for higher power devices. The characterization
process is conceptually quite simple."

Then there is the subject of S parameters, which is introduced early
by Motorola with this admonition:
"Many first time RF power designers, brought up on a diet
of smallï¿½signal sï¿½parameters, previously used for solving
small signal text book problems, assume these same
techniques are applicable to bipolar classï¿½C and classï¿½AB
power amplifier design."
This selection actually introduces the presumption above. We have one
poster here that violates this admonition with abandon - but with
regard to transmission lines.

When the poster pines further for a Large Signal S parameters:
"However, the authors are not aware of these parameters
being used successfully above a few watts of output power."

When Motorola actually gets down to design:
"The load line resistance is the optimum load impedance
for the internal collector node of the transistor, neglecting
the junction and parasitic device capacitance."
What a concept! Same as before, Same then, Same now.

The ONLY contretemps revealed by this tempest in a teapot is the
forced conclusion that a conjugate match was required (a common
mistake of not knowing the difference between Conjugate Matching and Z
Matching) which was in turn driven by higher frequency operation (much
of this is couched in the 900 MHz band) and parasitics already noted
above. The final and most compelling admission from Motorola is found
with their statement:
"It is up to the device designer to choose which
impedance gets published. One is just as valid as the other.
However, quite frankly, gain is what sells devices."

And of course this discussion will do nothing with those who utter
"you are not going to change my mind." ;-)

To be continued - no doubt.

Great! W2DU has made progress.

Frank also wrote:
"The problem with semi-conductor devices is that you cannot necessarily conjugate match because the device operating parameters may be exceeded."

True for certain voltages, currents, and drive. The maxima may not all be acheived simultaneously. It`s true for vacuum tube amplifiers too. The total device dissipation can`t be exceeded without reduced life expectancy.

Another caution is the difinition of "maximum available power". In an RF amplifier this is specific to a certain set of operating conditions. Maxium available power is with fixed B+ (or minus) voltage and drive. Current, too, is limited to non-destructive values.

Terman says on page 76 of his 1955 edition:
"Alternatively, a load impedance may be matched to a source of power in such a way as to make the power delivered to the load a maximum. (The power delivered to the load under these conditions is termed the avalable power of the power source.)"

Dear Lee,

I'm sorry to say that you aren't doing anything wrong. As was the case with earlier versions, the Package and Deployment software provided by Visual Studio 6.0 has a problem with Windows ME. I can't get it to work here either on my ME systems. The problem does not occur with Windows 98, Windows 98SE, Windows XP or Windows 2000.

I think I already created a workaround for the problem about a month ago and will have to remember what it was. It is really not difficult, but you do have to copy some system files into C:\Windows\System32\ in order to get it installed. If anyone else is also having this problem, please e-mail me privately and I will put you each on distribution for a workaround kit.

Frank wrote:
"I have trouble with the concept of "Reflection", how can charges (electrons) flow in both directions simultaneously."

The wave, or signal flowing in one direction is distinctly different from that flowing in the opposite direction. Upon reflection, the phase between current and voiltage prodiuced by the wave is inverted. Only phase of the volts or amps is inverted by reflection, not both. The phase relation between volts and amps is the key to the direction the wave is traveling on the line. It`s the wave which travels. The volts and amps are generated by the wave traveling on the line. The line is just guiding the wave.

The traveling forward and reflected waves, traveling in opposite directions on the same line, produce the familiar standing wave patterns through superposition of volts and amps. Transmission lines and the appurtenances used with them have no problem keeping values associated with the waves straight with proper design. A directional wattmeter can separate the two directions of travel wery well indeed. It knows one direction from the other by whether the volts and amps are in-phase or out-of-phase.

Best regards, Richard Harrison, KB5WZI

I quoted Terman, saying:
"The power delivered to the load under these conditions (a conjugate match) is termed the AVAILABLE POWER of the power source."

The match between source and load is the best it can be and can`t be improved when you have a conjugate match. A conjugate match is an empowerment but does not cause you to put out any particular power. That`s up to you.

Suppose you have a conjugate output match to a Class-B power amplifier you are driving with your SSB transmitter. Instantaneously, average power from the amplifier is following the modulation. A single steady tone ideally produces a particular output at at one radio frequency. Want more output? Increase drive to the amplifier. Want less? Reduce drive to the amplifier. You may have a conjugate match under only one condition, some conditions, or under all conditions, but given life`s usuall imperfections, I would place no bets, except against all conditions.

You might have to take the exam.

You don't have to take out the licence.

If you're as well educated as you claim, then you
could slip through all the exams with ease.

The M3/CB Fools' Licence is a gangrenous degeneration
of the technical pursuit (not a hobby) that is Ham Radio.

It is not and never was in need of "New Blood". If that
"New Blood " does not make its own gear then that "new
blood" is of the CB type and not the Ham Radio type.

Everybody had to start off with the RAE. That it was passed
with facility by otherwise-unqualified self-taught 14-year-olds
meant that there was never a need to lower the standards to
introduce the Novice (Now Intermediate) exam. That the
Novice was introduced means that there was _DEFINITELY_
no need to introduce the Fools' Licence whereby someone
starting out with no interest at all could have a "licence" after
only a two-day weekend course.

8-year-old children who do not even have the mathematical
background to work out resistances in series and parallel, the
most fundamental technical skill of any Radio Ham, are
getting Fools' Licences, thereby showing that one thing the
Fools' Licence is not, and that is a Ham Radio Licence.

I refuse to QSO with M3/CB Fools' Licensees precisely
because the licence is the thin end of the wedge leading to
non-technical Hams who are forbidden to build their own gear.

I exhort everybody who reads this post to refuse to QSO
with such licensees, not because of any personal issues, but
purely because of the threat that the M3/CB Fools' Licence
presents to Ham Radio if it is allowed to continue.

==========

- - - - and if that isn't enough, to further complicate matters, the internal impedance of the transmitter changes as the load impedance is varied in futile attempts to obtain a conjugate match.

But during such operations, according to your oft-quoted theorems, the internal impedance is supposed to remain constant.

I can't imagine why this conversation has continued for so many years by more or less the same group of experts. However, we do welcome the occasional newcomer. ;o)

Actually, the internal impedance, for a given load, is calculable under any operating-angle conditions of class A, B or C. But sadly, nobody has ever found a practical use for it! Although it can be brought into play in the design of plate-modulated tube amplifiers when there are two signal inputs and the load on the modulating device must be considered.

With a properly adjusted transmitter, at HF, either tubes or transistors, either single-ended or push-pull, it is purely a resistance of relatively high value. The active device generally behaves as a current source. The conjugative aspect then falls into disuse.

As active circuit analysts, you should be able to sort out the details for yourselves.

Tonight, I'm on Cabernet Sauvignon, a Bulgarian vintage. Just as good as the French stuff. Trade with our Eastern European friends must be encouraged even if they don't have as much oil as the poor, unfortunate, being bombed-out-of-existence for 13 years, Iraqis.

Hic!

Hi Reggie,

Such arguments are as juvenile as the claim no one can travel a
straight line because the earth is rotating under them. A quadrillion
miles of experience would suggest this too is trivial to accomplish.

Aren't you the one who is so charmed with the legacy of Kelvinator who
chimed that such chimera without calculation are the chatter of chimps
in the forest canopy?

Two years and my twinlead still sheds water like a duck.

At least in my case, the short time that I have been a Ham, I have seen more problem with water in coax than I have seen water problems with twinlead.

But we knew about those problems because the antenna didn't lose a bit of signal. It simply quit working at all!

Just a comment -

The design, from start to finish, of a linear power amplifier is based solely on a device's ratings - volts, amps, watts, etc.

Its RF internal impedance plays no part in it. At HF it is never specified by the manufacturer.

Even ARRL bibles don't mention the subject of Rint. It's superfluous. Does anybody know what it is? Give us some numbers.

As for conjugate matching - don't make me laugh.

If I migh say so Mr. Bean - You sound just like the sort of person that "Ham Radio" is trying to weed out and be rid of. Your attitude is in the minority.
With all the modern tranceivers on the market to-day it is not necessary to build your own.
If I had been permitted to sit, and pass all three stages of the license in one sitting , would that have made me a more responsible person ? I think not.
You are entitled to your opinion - and I respect it but please - everyone has to be allowed to start somewhere.

Pay bean no attention, he's not even civilized enough to suicide and put us all out of his misery. Neither his opinion or any other part of him has earned any respect. You're right, he's an embarrassment to the fraternity and we'd be better off without him or his attitude. (And certainly better off without his commentary.)

Source record: 85614

Hi, I'd like to extend the operable range of a Radio Shack cat #
63-1110 mailbox alert. It works with a small photo sensitive
transmitter mounted inside the mailbox. When the mailbox is opened
(i.e. a change of light level) the transmitter sends a burst (of what
frequency I know not) to the base unit. The indoor wall-wart-powered
base unit with a 11" antenna flashes an LED and beeps when it receives
this signal.

The directions say the transmitter should be max 150' away and in line
of sight. Well, I'd like the thing to work at 275' and slightly out of
line of sight --around some trees and over a small hill.

I tried hooking the base unit antenna to the center wire of coax that
goes to our rooftop TV antenna but that didn't work. I can't quite see
the top of that TV antenna from the mailbox.

I'm getting the impression that I should find some way to boost the
transmitter signal. Any way to do this? The transmitter is powered by
2 3V lithium batteries. There's a Radio Shack provided parts list on
the web but I can't make much sense of it.

One thing I might try: Our detached garage is about 75' closer to the
mailbox than our house. The apex of the roof of the garage is probably
in line of sight of the mailbox. There is existing conduit for phone
wire from the garage to the house. I could probably run a long
"antenna" wire from the garage roof apex to the base unit inside the
house, but I wonder if the resistance (oh, right --impedance) of long
wire might throw cold water on this idea.

I know only of smattering of electrionics and certainly not much
analog. Any suggestions appreciated.

--zeb

Bob,

This is a good example of why I don't like (or use when possible) installer programs/scripts. If it is not absolutely required, most users would generally prefer a simple zipped executable, required DLL's that are not common and a simple text description of how to create a link to the executable for folks who don't know how to do that.

I use Delphi for programming simple tasks and in my humble opinion, the days of registry entries (to save disk space), INI files in Win or win\system (because that was the default for many) and like "conventions" are past. Hard drives are large enough not to have space worries, and having all required files in one folder mean the simplest of install / delete procedures.

Sheesh, glad I got that off my chest.

Returning this newsgroup to its normally scheduled programming...

73,

phil

Reg, G4FGQ wrote:
"The active device generally behaves as a current source."

As Reg also wrote:
"I can`t imagine why this conversation has continued for so many years by more or less the same group of experts."

Agreed! Reg seems to have answered his own question.The same people recite the same arguments in hopes their view of reality will be accepted. Fat chance! Time has inured them.

Reg has faithfully proposed constant-current behaviour from all vacuum valves and transistors as I recall. I agree that most of these devices have extremely high plate ond collector resistances as linear amplifiers. Current through them is almost constant regardless of anode voltage.

As most transmitter power amplifiers exceed 50% efficiency by a good margin, these devices are not operating as Class-A linear amplifiers. They instead operate as HF switches. These are turned-off most of every cycle and are only on for short pulses. Harmonics and other noise is cleaned up by output filters. It`s the only thing which makes the output linear.

During the output device`s conduction, its saturation volts are very low and its current is very high, giving the device a very low impedance while switched-on. You may not infer a low impedance from the d-c volts and amps feeding the final amplifier. These are the averages, almost, of the device amps. The device saturation volts sre what counts toward its dissipation and loss. The transmitter usually has no built-in indicator of saturation voltage. It wouldn`t read much anyway.Device impedance depends mostly on its ratio of off to on times. This is a form of lossless resistance. Dissipation is zero in a sewitched-off device. The d-c volts and amps are related to the output device(s) internal impedances used as a switch when the transmitter output is considered. A high voltage and a low current accompany a high internal impedance but they won`t be nearly so high as the spec sheet plate or collector resistances.

We have d-c power input to the amplifier. We can measure HF power output. The difference is dissipation, but loss resistance does not represent the total source resistance because we have non-dissipative resistance in the device off-times.

There have been measurements of transmitter internal output impedances which indicated that they did indeed match their loads. I have not done

it myself but have no reason to doubt the reports.

Best regards, Richard Harrison, KB5WZI

FIRST: You really ought to rephrase that subject line. :)

As to the mailbox activity whatchamcallit, try putting a proper directional antenna on the TX unit (the mailbox transmitter.) I vaguely recall the device. I have no clue what frequency it may use, but I'm sure someone here will know it. Then wire a directional antenna on the RX unit (the house side.) You might also try placing the entire receiver at this garage you speak of, and use a 4 pair cable to the house to feed the LED, buzzer, and reset signals back to the dwelling. You will likely have to buffer or isolate these with either transistors or relay circuits to overcome the loop impedance of the cable, depending on how fussy the box is.

Even though it might seem so, this is not likely to be too complicated.

Have fun!
Pat

Dear Phil,

Gee, Phil, you won't get any argument from me on that. In fact, were it not for the fact that I enjoy coding in VB instead of VC++, I would be doing this in VC++ and we would all be looking at teensy executables and a 10X simpler installation package.

It was a gigantic surprise to me that Windows ME is so problematic. However, to be honest, I think the problem really lies in the fact that I do my development in W2000 Server. When I do my development in W98 or WinME I never have these problems. (I also did not have these problems when I was coding in the older VB3.0, which had yet a different packaging wizard.

My biggest reason for not going the route that you suggest is that for 90 to 95% of the users, the packaging works without a hitch. And I can live with those odds. Having to put together a set of instructions telling people that this file goes into this folder and this file goes into that folder, etc., can be just as counter-productive, because for

many people, file management is an anathema.

I'll work it all out eventually, even if I have to move my development platform to one of the Win ME machines.

Anyway, thanks for the encouragement,
73

Hello,
I hope I'm in the right newsgroup.....

I am totally remodeling my house.
The walls are gutted down to the studs.
I want to run any and all appropriate wires and cables before the
drywall goes up.
I want to receive UHF and VHF TV signals for my TV.
Most people now get their signals via cable or satellite.
I would be happy with just six channels or so.

What kind of cable should I run ?
What type of amplifier should I have ?
Rotor type ?
What are good antenna brands ?
Model numbers ?
Anything else ?

Thanks,

Hank

NO, not the correct group for TV, satellite TV or home cabling ... try
rec.video.satellite.tvro or comp.dcom.cabling or
http://www.remotecentral.com/cgi-bin/mboard/rc-sat/list.cgi?2130

Home cabling today (computer network, TV, etc) is referred to as structured
wiring.
http://electrical.bobvila.com/Article/371.html

http://electrical.bobvila.com/Article/372.html

http://www.ehow.com/how_12212_make-pre-wiring.html

http://www.tvidish.com/builders.html

Remember that "off the air" VHF/UHF analog signals are due to be replaced by
Digital TV over the next 4 years. I would wire for satellite cabling
standards, if you don't have a local CATV company.
DIY TV cabling
http://www.dba.org.au/uploads/documents/Consumer_D.I.Y._140802_amend.pdf

http://www.smarthome.com/coaxcable.html

Some other links
http://www.satellitetv-hq.com/hqguides/get-satellite-tv.html#installation

http://www.starkelectronic.com/

The other choice is to just pull the plastic tubing for the cable (with a pull string) and pull the cabling later -- without ripping up your walls. Check with local building and inspection codes for acceptance in your area.

Benefits to Homeowners

Homeowners or tenants are exploring the full spectrum of residential technologies available today and most certainly will continue to do so in the future. Entertainment, security and environmental controls are only a few of the highly desirable attributes being sought by homeowners and tenants. In addition, there are other convenience offerings and features, e.g., energy-efficiency, high performance in-home networking, internal or external digital video/audio systems to name a few. Enhanced capabilities for SOHO's, Internet access or telecommuting are obvious, and are among additional benefits to be enjoyed by residential users, all enabled by a TIA-570-A infrastructure in the home.

Hi Hank

Since your doing a full gut rehab anyhow!

Here are a few ideas that we often do during upscale renovations.
The cost is negligible before the walls go up.
In the den, we run a 3/4 PVC conduit from a pull box in the den, both upwards to the attic and downwards to the basement for future unknown technological advances. We sometimes do the same thing in the master bedroom.
All homes are daisy chain wired to every room with two 4 wire telephone and two 6 wire shielded cable each in their respective pullboxes, plus from the central utility area two 75 ohm coax are run to a pullbox in each room.
In addition to the AC electric, from the utility area we often install low voltage DC wiring to bathrooms, bedrooms, hallways, etc. for emergency lighting. And on rare occasions piping for oxygen to master bedroom, kitchen and den.
And the security service wiring to doors and windows.
And the zone controls for HVAC, etc.
If you intend on having a hobby room, it's nice to have it vented and plumbed as a wet bar as well.
Now, if your a HAM!
Don't forget the SHACK, hi hi, it should have the very BEST of all amenities and grounded cable routes, etc.

TTUL
Gary

Robert,

I would suggest to create your 'install.exe' on the oldest (W-95, -98) system you have available and on which the software is running. When creating your 'install.exe' the (old version) dll's and ocx's for this 'old' system are included in the package.

Old version dll's mostly are upwards compatable for running on 'new' systems, whereas new dll's sometimes contain new 'features' which are not compatible with the older systems.

However, don't forget to test on your most up-to-date machine.

At least that's my experience using 95, 98, Me and 2000

Arie.

"Ham Radio" is most certainly not trying to "weed out"
those who seek that technical standards be maintained,
and who encourage others to be technically motivated, for
that is what Ham Radio is all about.

CBers and CBers-Masquerading-As-Radio-Hams might have
that sort of agenda, however.

I append a short article to assist you in disambiguating the two.

"Simon Smith" <s.Smith@btinternet.com> wrote in message

> Radio" is trying to weed out and be rid of. Your attitude is in the
> minority.

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical

development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,
competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

The usage of a pathway (conduit, etc.) is always a good idea for future additions for your structure home cabling (especially heavily used areas)

"Daisy chaining" is NO longer the acceptable physical installation practice for home structured cabling (EIA/TIA 570-A standard). This was the practice by the Bell Operating companies for telephone cabling before its breakup in 1984 .. and is mentioned as a legacy method used before the adoption of the EIA/TIA standards. The standard also addresses 75 ohm video cabling (TV, etc.) as well as have foundation standards (568 and 569) more suited for larger commercial or business installations.

The standardized practice for structure cabling in new installations (and remodeling or major retro-fits) is for "home-run" wiring from each outlet from a central location (cabling in a physical star topology) with a distance limitation of no more than 100 meters from equipment to the telecommunications outlet. BICSI also performs certification of structured cabling installers (electricians, contractors) for both residential and commercial installations.

Do a Google search on EIA/TIA 570-A ; structured cabling or BICSI and you will find the necessary information. The major cabling vendors (Leviton, Systemax(old AT&T cable), etc.) also have this pertinent information.

I only point this out, since I am a professional consultant in this area --- and find the "daisy chain" approach for physical cable installation still practiced and approved by municipalities and contractors ... UNAWARE of

these standards ... now 10 years old and reviewed on an annual basis through the EIA and TIA organizations.

I did some measuring and I have room to put up a loop 267 feet long, making it an 80 meter loop. Would this make a good antenna for 80 thru 10? I'm currently using an Alpha Delta DX-CC mutiband Dipole.

Thanks,

Bill Cherepy

I second the comment re: daisy chaining telco wiring.
Several months ago I did a self-install of DSL here. And, from past
'projects' putting in 'extra' phones in various rooms, I knew the
hay-wire daisy chain scheme I had (circa. 1977) -- going all 'round
the attic -- thence to the finished basement and snaking through the
stud walls there. What I ended up doing was installing my own NIB
(Network Interface Box) just downstream from the telco NIB. There I
installed a DSL filter on the daisy chain line headed for attic.
Ahead of the DSL filter I installed a new line and pulled it into
the home office. Not a lick of trouble with DSL since day 1.

Going the other route: installing DSL filters at each outlet
along the daisy chain did *not* give me a warm and fuzzy feeling.
I felt there would still be plenty of opportunity for RF noise
to get into the long daisy chain (read: random wire antenna) --
which would degrade the DSL operation. Too, I was concerned
about the interaction (both ways) between the DSL signals and
my amateur radio activity.

Just last week I did a DSL install for a small, local real estate
office -- two agents and a receptionist -- 3 PC's (that were
here-to-fore freestanding.) They had a punch-down block in the
basement for 2 'voice' lines and 1 'fax' line -- with separate lines
running off to phones and fax. Simple install: I installed a DSL
filter on the fax line (the line carrying DSL) right at the punch-down
block -- breaking out a new, short line to the DSL modem/router and
hub thingies which I mounted on a shelf close by. From there it was
'simple' to pull CAT-5 cable to each of the 3 PC's upstairs.

I'd say: pay the telco to put in a punch-down block -- and run
two lines in from the street or alley (even if you only plan on
using 1 line -- now.) Then run 2-pair from 'everywhere' in the
house to the punch-down block -- but tie back (store) the ones
that are not (yet) in use.

Thank you, Arie. I fully agree. I actually test both the installation procedure and the performance of the installed product on Windows 98SE, Windows XP Pro, Windows ME, and Windows 2000 Server. Those are the only Windows machines that I have available. I.e., I do not have earlier than W98SE.

I already knew that there were problems with Windows ME. I had worked out this problem on the previous release, but simply forgot to do it on this latest release. I got lazy - Hi!

You could make your own 1:1 balun for a few bucks, and place it on
either side of the tuner. See W2DU's article:

http://home.iag.net/~w2du/Reflections2Chapter21SomeAspectsoftheBalunProblem.pdf

Yes, one DSL filter at the "head-end" or entrance panel can address all of
the distribution issues with DSL. In fact, I prefer to keep the DSL modem
and router AT the head end.
Surplus network equipment that is more than adequate for home networking is
almost being given away these days.

I live the Leviton system, but have used others, as well as the original
plywood backer board and 66-block / 110 block installations

Leviton has a very good book (Adobe Acrobat that anyone can download) that
should be required reading for the planning stages. It's normally $ 10 BUT
the downloadable Acrobat copy is FREE
Covers ALL of the diagrams and techniques the are compatible with the
EIA/TIA standards.
This is a MUST for your local building contractor or DIY installer.

The difference between RG-6 and RG-59 coaxial cable

What's the difference between RG-6 and RG-59 Cable?

RG-6 and RG-59 are two types of coaxial cables that can be used with F-type connectors for the distribution of RF signals for cable TV (CATV) and satellite (broadband), and BNC connectors for closed-circuit environments and data transmission (baseband).

RG-59 is a lower grade of coaxial cable, consisting of a small center conductor, a small insulating dielectric, and typically, a single outer shield. It delivers acceptable performance for all of the above-mentioned applications.

RG-6, on the other hand, has a larger center conductor, a dual or quad shield, and a much larger insulating dielectric, thus ensuring more bandwidth and a lower frequency loss per foot. It delivers exceptional performance for the above-mentioned applications, and is considered the cable of choice for digital TV.

Quality 3/4" exterior grade plywood can easily serve as a centralized wiring center (TV, telephone, computer network) for service demarcations and termination point for the house wiring (coax, UTP and fiber), in some cases -- space or esthetics dictate other approaches or solutions for a centralized wiring center.

When you do not have no basement, need a "flush mounting" cabinet (that fits between standard 16" stud construction) and have esthetic considerations within the house .....
I like to install and use the Leviton Structured Media Center.
http://www.levitonvoicedata.com/catalog/BuildPage.aspx?BuildPageID=223

I installed one of these Leviton enclosures last year at my brother's home (1-story ranch) which was built in the mid-1990s. Leviton SMC enclosures are available at Home Depot, Lowes and numerous electrical distributors that carry Leviton (e.g. TriState Electronics, Mt. Prospect, IL).

Installed the Leviton model 420 (large unit) flush in his garage wall. This larger enclosure allows for the eventual incorporation of a security system and a whole house audio/sound system.

Today, the SMC supports two Category 5e unshielded twisted pair (UTP) cables and 1 RG-6/U quad shielded coax cable terminated at a telecommunications outlet (every room of the house). Specific room locations (e.g. video/sound media center, home office/computer area; large family room) were wired with additional jacks or outlets to accommodate specific equipment needs, future growth and the ability to move furniture within large rooms (and hide cables).

The installation was standardized on telecommunication outlets from Leviton's QuickPort Decora Multimedia Insert collection. This matched the

existing Leviton Decora electrical switches and outlets (in both color and design - esthetic considerations) throughout the house.
I primarily used the 4-port inserts with some 2 and 3 port inserts at specific locations of the house for specific usage.

Complete installation took about one week (2003 Thanksgiving week):

Maintain all telephone, CATV, home network and Internet services during installation (This does contribute to the longer installation timeline)
Installation work could only be performed between 9 AM and 5 PM, with mandatory clean-up tasks at 4:30 PM (This was due to the week chosen and specific hosting and family commitments)
Rough in Leviton Structured Media Center (SMC)
Pull new Category 5e cables (about 24 runs)
Pull new Quad shielded RG-6/U coax (about 12 runs)
Reroute high quality CATV cables for reuse (3 runs).
Route all cabling through attic space and establish primary cable pathways within attic space (minimizing pathways adjacent to home electrical cabling)
Install multimedia (coax) 3x8 distribution unit (supports satellite, cable and video inputs)
New service drops (CATV) to SMC from 2 local providers (Newnan Utilities and Charter cable)
New electrical circuit run for main circuit breaker box (power to the SMC)
Reroute Bell South telephone drop and demarcation to SMC enclosure

Remove original owner's Quad (obsolete 4-wire) telephone cabling throughout house. Former owner was a building contractor who installed existing cabling infrastructure (He was clueless on structured cabling or standards). BTW, if you get DSL services many Baby Bells will not support internal quad cabling .. and either wire to specific point or advise you to rewire the house.
Remove existing (poor quality) RG-59 coax and distribution (splitter) system.

Full 100 Mb (Fast Ethernet) home network and CATV services are supported throughout house, with 802.11(b) "WiFi" capabilities added this past summer.

The only way to go, a "Plug-n-Play" house.

# 3354. Feeding 30 Mtrs into a 40 Mtr Dipole - Losses ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-09 21:37:18 UTC
From: Gary
Message-ID: <cvghr051bk9fr542fk8d2j5ao5i09cfivt@4ax.com>
Source record: 85550

I've got about a 70 foot +/- run of RG-8X that I use to feed my 40 meter dipole. I also use the same feedline and dipole through an MFJ-949E tuner to operate on 30 meters with. Out of curiosity can someone tell me about how much a a signal loss I've got compared to having an antenna that's actually cut for 30 meters ?

Thanks in advance.

73 Gary K8IQ

## 3355. Balun/Unun help please.

Hi there,

I have a marine MF (1 to 7 Mhz) transmitter with only an antenna "screw terminal" for a long wire connection on the back of the set, rather than an SO239 or N type, and the set itself being grounded with copper sheet to a decent earth. My problem is, I need to feed an MF whip on the roof, some 50 feet away, through the building, offices etc, and dont really want the EMC and Health and Safety problems that would arise from 400W PEP happily radiating indoors with the recommended wire lead-in. So I'll need to use a feeder. I have decent low-loss coax (LMR type) but how do I couple it to the set? ..and to the whip (just a long-ish wire in fiberglass) at the other end. Im thinking an unbalanced to unbalanced transformer at both ends of the coax should do it, with both the tower and the set in the workshop grounded but the coax outer isolated. I have toroids that will do it, but how should I wind them? Im thinking MF ununs could be made by winding 10 or 12 turns of coax on suitable toroids. Is this reasonable or am I way off.

ALL suggestions, even those calling me a muppet :), will be very gratefully received.

Thanks, John G0WPA.

I assume you've downloaded the free Service Pack 2 for Windows XP. It
adds all kinds of security features.

On Windows XP, you can go into the Control Panel to "Windows Firewall"
and activate it, if it is not already activated.

You can also go into Internet Explorer, to Tools, to Internet Options,
to Privacy, and increase your security to hold most, if not all,
Cookies in check.

Yup. Heard on a computor discussion that XP was as open as a barn door and over time
the computor got slower and slower. They also stated that Netscape apparently not
subject that much to attacks Didn't take much notice at the time until I bought a 3 Gig processor
and after a while checked how much junk had unknowingly been attached to it, one of which
had slowed me down till it shut down completely!
I wouldn't be surprised if this newsnet did add junk every time you linked to it.

I lost confidence in netscape when aol took it over.
Try mozilla firefox (it is free)
or
Avant browser (also free)
--- also download the free firewall (zoneAlarm) from zone labs
and-- free antivirus software (AVG)
and you can replace microsoft office with OpenOffice .org
and if you can find some scrap wire, we can talk about a free antenna
:-)

Hi Gary, According to my calculations the feedline loss is around 90%, so if you are running 100 watts, and the tuner is lossless, 90 watts are lost in RG-8X. The good news is 10% efficiency is only 1-2 S units down from 100% on the recieving end. The bad news is, no tuner is lossless.
You will have loss using a 40m dipole on 30m. Does that satisfy your curiosity:-)?

You may be asking for help with a solution that isn't necessary, and also may not be sufficient to accomplish what you want. If the transmitter is capable of matching a variety of loads, it may be sufficient to simply run the coax from the transmitter to the roof, connecting at the transmitter end to the screw terminal (to the center coax conductor) and the transmitter's ground/chassis (to the outer coax conductor). At the roof end, connect the center conductor to the whip, and the outer to a ground plane...at least some radial wires, if there is no large metallic plate to connect to. But how will you know if the transmitter has properly matched to the load presented by the coax+antenna? It's usual to have some sort of tuner (perhaps already in the transmitter?), and perhaps an antenna at the other end of the coax that has a reasonable feedpoint impedance. It could result in a fairly high SWR on the line and still be reasonable, so long as the transmitter can match it. But I don't see that an "un-un" would do you much good in this case, unless you need galvanic isolation between the transmitter and the antenna. -- It also may be convenient to mount a different antenna connector to the transmitter, either in the existing sheet metal or on a small bracket attached near the existing screw terminal.

Cheers,
Tom

>else will be corroded before you know it. Perhaps stainless steel
>aircraft cable?

Absolutely. Replace your 50 feet of copper with stainless steel wire. Mount it carefully and you'll get 10 years out of that. Keep the tuner. Its one thing to have resonant lengths or traps on the harmonically related ham bands but someday, when the swell is 25 foot in a force 9 and your drifting towards rocks, being able to instantly tune and call on 2182Khz or one of the higher distress freqs may very well save your life, believe me, Im a lifeboat man. But, taking others views on board, as part of your regular planned maintenance (you do that dont you?), take the lid off your transciever AND tuner to check for corrosion, youll recognise it as white flaky stuff where the shiny bits were last year! Other than that, your tuner is no more likely to breakdown than anything else on your boat.

>You may be asking for help with a solution that isn't necessary, and
>also may not be sufficient to accomplish what you want

Thanks Tom, you may be right. I should probably just feed the whip with coax and take some field strength measurments to assess the extent to which the outer is radiating. There may be no problem there at all!

>It's usual to have some sort of tuner (perhaps already
>in the transmitter?)

Yep, theres an aerial current meter.

>It also may be convenient to mount a
>different antenna connector to the transmitter, either in the existing
>sheet metal or on a small bracket attached near the existing screw
>terminal.

True, after all its already an unbalanced output!

>But I don't see that an "un-un" would do you
>much good in this case, unless you need galvanic isolation between the
>transmitter and the antenna.

Well, thats the problem, its to run in a cable tray with a lot of other feeders, alongside video!!!, radar control and various VHF receive cables. Maybe im being paranoid about it, but Im looking to eradicate every trace of RF from the outer of the coax, thats why im looking at isolation with chokes. But as you suggest, maybe there wont be a problem, I'll try it without, first!

Many thanks tom.

Yes, thank you..I have been thinking about modifying an existing tuner with the balun on the output. The problem is that ALL components must be isolated from ground. I suppose I could pull that off, but it is not as simple as you might think, especially with a tuner that uses a tapped inductor in a T match. I t would probably be easier to float a roller inductor than a tapped inductor because of the switch. The caps are usually above ground already in a T match, so thats not a problem. I'm thinking about it, but it would be nice if there was a good affordable balanced tuner out there.

Netscape has its own problems, but not like the MS suite.

I only have to look at your headers to see you use Outlook Express
which is a piece of trash. It has the worst reputation as being a
virus whore.

> I wouldn't be surprised if this newsnet did add junk every time you linked
>to it.

News groups might be mined for emails for subsequent Spam, but there
is nothing in the NNTP (protocol) that would allow anyone to attach
anything to your computer. This kind of stuff comes automatically as
a customer enhancement by MS for IE and OE users and arrives by email
or through visits on the Web. There are no trojan horses, viruses,
cookies, advertising (pop up windows that is, there is still Spam of
course) or spyware that can infect your machine through participating
in newsgroup activity.

I've gotten what looks like a potential virus sent to me because they
got my name here. WAMU frequently is part of the subject heading or
in the message. This may not be a virus (as the ISP certifies it is
not) but rather a Phising link. No problem, my mail reader is not
going to run it, open it, or do anything without my permission. I
simply trash that stuff. Been doing that for 10 years with either
Eudora or Agent and never been burnt except once (trusted a friend) -
then fixed that the next day after the infected Comcast ISP servers

stopped thrashing themselves to death. Yup, they were using MS servers.

For anyone seriously interested in the mortar between their firewall bricks, go to:
http://grc.com/default.htm
and page down to the heading "Your Three Musketeers"
There are at least a half dozen security checks there that can inspect your machine for back doors and potential hacker access. Very simple software, loads fast, runs fast, and says quite plainly in English, "You are Safe" or "You are in Trouble."

Hey Art, here are my suggestions:

1. Get Zonealarm, Preferably version 4.xx

3. Get Netscape, or one of the flavors of its engine, such as Firefox.
Use this to get your mail, and read newsgroups too.

4. Start Internet Exploder one last time. When Zonealarm pops up and
asks if Exploder can have access to the net, then click "remember" and
deny it permission.

By denying IEEEEEEE! permission to ever access the web on your machine,
you will be doing humanity a great favor. Same for Outlook.

If you get the paid version of Zonealarm, you can have it delete all
cookies every day. You can also select ones you want to keep, if any.

5. Consider using a proxy server such as Proxomitron,(freeware)
especially if you are on Cable, or DSL.

6. Always change the updates feature of your computer so that you
manually do the updates. If you automatically update, you will find that
Microsoft may make your computer more secure by making it less
operative! 8^)

Hope this helps!

- Mike KB3EIA -

Hi John,

If you are adventurous enough to open her up, replace the "screw
terminal" with an honest SO239 (or "N" or "BNC" or "RCA") bulkhead
connector. This will require you to probably open up the hole to
match connector dimensions and perhaps drill the bulkhead mating screw
holes. None of this is terribly hard.

Or simply get a SO239 (etc.) bulkhead connector and solder two wires
to it: one into the metal through one of the mounting holes, the other
to the conventional center conductor solder cup. Connect those two
wires to the set: the center conductor wire to the existing "screw
terminal" and the mounting hole wire to the chassis (add a sheet metal
self tapping screw nearby the "screw terminal", and make sure the
screw does not puncture anything on the other side of the chassis
face). Insulate exposed wiring with tape. Leads should be kept
short, less than 4 inches or so. Make sure these connections are
hardy, one lead open can take you right back to RF in the Office.

As to your other question, add a 1:1 Current BalUn (or UnUn if you
prefer) at the antenna end of your cable. Make sure it is adequate

for your operational frequencies.

Interesting.
So, do you still use Windows with a replacement for Outlook Express
together with the link that you pointed to or do you pay for extra computor
protection?
I must admit that I thought everything was as one should expect until I used
the free ' adware' to check how clean or dirty the computor was and I was
really shocked. Fortunately with the help of an inserted disc I am able to
run my antenna programs in what I see as a DOS emulator which allows me to
use high speed processing without the fear
of outside interference and slow down. I have heard that Netscape has its
problems but does not have enough useage
to attract bad guys and commercial collectors. Tho I have done computor
programming in Fortran and the like in the old days when we used punched
tape I must admit to being totally illiterate when computors changed over to
pre caned programming to which I turned up my nose too, only to find I was
quickly left behind and not adaptable to change.
Regards
Art

Mike
EVERY thing I am getting is a real help and an education for me
I did get a private E mail that high lighted a version of Netscape that with
a press of
+ or - you can make reading news much easier to read by enlarging the
script !
I am sure that there is more than one old guy like myself on this newsgroup
who would
apreciate such an aid . With respect to the advice coming in, I wonder how
many have
checked their computors with 'adware' to verify the veracity of what they
have stated?
Regarding the aditional purchase of 'Zonealarm' , I am trying to resist
placing more
money in to computors e.t.c.when the origional suppliers of programming
were derelict
in providing adequate protection in the first place, but I am not totally
stubborn to the idea
of admitting defeat.

I abandoned the home versions of Windows long long ago (I use Win2000
Pro). I got it pretty cheap as a computer upgrade, all I had to do
was buy some hardware to qualify, and I bought the hard disk that I
have it running on right now, in the old system (just added it as
drive two, and use the original drive for storage).

I have NEVER used Outlook Express. I bought Agent after using Free
Agent for a year. I wanted to combine my News reader with a Mail
reader that had very good filters. Those filters, once I trained
them, act like bug zappers and automatically trash Spam. I have 8
filters that steer acceptable email to different folders; I have 10
filters that deletes porn; I have 4 filters that ignore odds and ends
that I can look at if I want (but ends up in the trash anyway). Agent
is $35 and I've been using it for 8 years.

I am also using Firefox now (it lit up in seconds where Netscape
stumbled along). I also use Agnitum Outpost Firewall (free version).
It always lets me know when some piece of trash wants to call home. I
say no, and then take out the trash.

That has nothing to do with it. It is the "features" of IE and OE
that are the back doors to the system. Do you want to share your
printer with the world? MS thinks you do, and has designed this into
their OS as a special feature for your "benefit."

>Tho I have done computor

It just runs faster. Being bigger means no one person really
understands it all. When the operating systems were 15,000 bytes big,
you could figure it out in a weekend. Multiply that by a million
weekends. Only Chinese teenagers have that kind of patience.

As a ham of over 25 years experience and most of those using a ladder line fed 80 meter doublet, I would highly recommend procuring an old Johnson Matchbox. These units were made back in the '50s, very well made and will match on all bands, except 30 meters, from 80 thru 10 meters.
They are a link coupled transmatch, made excusively for use with ladder line or twin lead.
There are a lot of them advertised on eBay.

MFJ has at least a couple of "balanced" devices that place a choke type
balun on the transmitter side of the device. As I recall, MFJ uses a piece
of coax with Teflon dielectric that is surrounded with unknown material.

Ok,Ok,Ok e.t.c
Since Mike gave specific directions as to what to do to get the job done so
I am leaning towards
most of what he suggests ( don't under stand the proxy server bit tho).
Thanks to everybody tho for their inputs including those you gave a better
choice to the one that I am leaning towards. Need to get back to antennas or
swr before the net policeman scolds me for using this net for unofficial
postings
Best Regards.
Regarding operation.. they vacuumed all the parts that was left of my
fragile
gall bladder after it crumpled .Unfortunately they got nosy and took a
sliver
of my liver among other things and are suggesting that I must be some
sort of hidden alcoholic ( I am teatotal but they take some convincing,
tho I do admit
to a glass of wine for toasting at a wedding some months ago)
Maybe we can attribute the
internal mayhem to this laptop and Windows XP, sperm count doesn't matter
now.

John:

1 to 7 MHz is almost 3 octaves, and no simple antenna is going to present a usable impedance match to the coax over that
range. Are you operating a spot frequency, a narrow band, or do you need the full range? If the latter, then you
better look at remote antenna tuners, although I do not know of any which go below 1.6 MHz. Because, no matter what
chokes, etc. you install, you will never decouple the outside of the coax from the antenna field enough to be able to
successfully run it in a tray with low level signals. Been there, tried to do that. One thing you will eventually
learn, forget the half-antenna (whip) and put up a dipole. Then, you have a fighting chance to keep the antenna
currents in the antenna where you want them, and not on the outside of the feedline, which thinks it is the other half
of the antenna when you employ a whip, even with radials. At 1 MHz, the radials need to be almost 300 feet long.

>
> Thanks in advance.

For 30M ops I suspect that you'd be much better off if you temporarily shorted the center conductor and the braid of the coax together and turned the feedline + dipole into a top-loaded vertical. Build a "shorting widget" out of an SO-239 in order to be able quick-change bands (sort of). On 40M feed it as a dipole as usual. On 30M install the "shorting widget" on the 8X 259 connector, feed the widget from the "random wire" connection on the back of the 949E and tune up. Attach a couple 25 foot radials to 949E ground post.

I've been running Eudora since Win 3.1.1 days, beautiful, just plain clean, simple and to the point beautiful. Even though it doesn't have many of the bells & whistles Outlook has. I don't need Microsloth's autodialer, etc.

Since you're running Agent maybe you can answer a question Richard. Backgrounder: 'Wayback I used Free Agent which worked like a champ. In those days I accessed USENET via my ISP's paid subscription to some second-tier USENET servers. My ISP is a litle dialup/DSL store-front operation here in the neighborhood. Under circumstances and for reasons long lost in my brainbone I've been accessing the newsgroups via Google instead of his service for a number of years. Which is getting *really* annoying. In the meanwhile my ISP dropped his old USENET subsciption by virtue of non-use by his customers which leaves me dangling.

I'm very inclined to get back to using Agent even if I have to pay for it (sob!). How, exactly Richard, do you access the USENET groups with Agent?

It sounds like you have an older marine transceiver with built in
antenna coupler, which is not uncommon. A tech would install the radio
and match the whip (non resonant) and random wire feeder by choosing
coil taps and tweeking a cap for each channel. The channel selector will
now select the correct coil/cap to match properly the antenna. If the
radio or antenna is moved you must retune the network to match the
antenna again. If this is the case here you would have to bypass the
coupler section and remote it to make the radio happy feeding coaxial
cable, probably a big project.
Mike

>Agent?

Hi Kelly,

The folks at Forte (agent) are also in the business of providing their own premium news feeds over the net for as low as $3 a month that would easily satisfy a text based interest. Visit:
http://www.forteinc.com/apn/index.php

You could still, easily get by on their current FreeAgent. Very robust and still cheap for the full featured version.

Access comes via Comcast. This means I have to come in through the connection. I also have an ISP who provides me a Primary Shell for one of my several Web sites, and I can get into their News Feed over the net. My Primary Shell "can" cost as low as $7 a month if you pay by credit card in 6 month blocks or you can get a modem connection for $16 a month (in 6 month blocks), anyway visit:
http://www.eskimo.com/

I pay much more, of course because I'm on high speed (not to speak of also having three web sites to support) - but then, its my work.

I'm not sure if that answers your question as to "how" I use it. Their help function answers that, but if you have configuration questions I can certainly help - I did that for Walt a couple years back. He sometimes curses Agent, but he isn't plagued by virus.

>--

All very good points. What it comes down to is that a whip always needs some kind of ground/radials/counterpoise connection at its base. You need something to feed the whip *against*.

Older marine transmitters is that they tended to take a good 'ground' return for granted, so they only provided a single terminal for the antenna wire. If you convert to a coax output, it won't make any difference unless you have something to connect the shield of the coax to, out at the base of the whip. That "something" has to collect all the RF return current from the whip itself... and if it doesn't, all the building wiring and the outside of the coax will collect those currents instead.

If you think of your office building as a very small 'ship', but without the benefit of all-metal construction or a decent salt-water ground, this is not a promising situation. In today's electronic office environment, I'm afraid you are likely to be fighting a perpetual losing battle against EMC problems.

If this radio link matters, you'd do better to find another location for the transmitter and antenna.

The loss on coax with that kind of a mismatch is around 90%. You are
better off with open wire feeds, especially since you have a tuner
available..even if it is MFJ ( Hi ).
An open wire fed 40 meter dipole will produce a fine multiband
antenna..take that to the bank!

In the off chance you are serious -- the minute you transmit on a Ham band -- the locals will look you up in the FCC data base and query you - if you are not licensed they will turn you in to the FCC. It is quite easy to determine if you are a licensed Ham. Finding a transmitter location is also no problem. The fines are very very severe.

If you doubt that -- look up FCC violations on the web. See URL: http://www.eham.net/articles/1744

Driving without a license is a sure way to get into deep trouble as is transmitting without a license on the Ham bands

This has happened in our area several times -- Hams are very protective of their bands.

Why not just buckle down and do things right. The tests are easy.

Hi Wes,

I gave up on Virus software years ago too. They always seem to be one
infection behind.

The only time I got the sniffles would have had the bug waltzing right
by it undetected. If that's the level of competence I can get for $50
a year, I wonder what it would have cost for a package to have caught
that last bug that got me.

Anyway, those utilities offered by grc.com disinfect the system by
strengthening the natural defenses instead of trying to look at every
byte coming in the pipe. Virus-ware can be cpu hogs - or at least
they were when I sampled them a long time ago. When I watch my
friends grow moss waiting for their systems to boot beneath their
load, I must say that my bias remains confirmed.

Hi gb

I agree!

I also was not quite clear in my statements either.

We only daisy chain each rooms telephone circuits from a central locatiion using loops in the pullboxes, having blank cover plates over those pullboxes until it is decided which one will suffice for the room furniture layout.

For computer we usually use the 75 ohm cable direct to the central area for internet, and for internal networking the 6 wire cable is used. It too runs from each room to the central area. If the internal network only goes to rooms B and D only those two connections are made in the central area.

In my house I have a shielded twisted pair going to each room, in each room it is daisy chained to all possible outlets, at least 1 on each wall, in some cases two on a couple of the walls. Unless it was used at one time, there are no connections within the pull boxes.

However one decides to handle their wiring and extra's it's better to have and not need than to not have at all.

Price is also a consideration! Running 6 telephone lines from a central area to each room in the home can get quite expensive and overly redundant for most home installations.

In addition, some cities charge 10 to 13 bucks extra on the permits for each pullbox installed, even when those pullboxes are used for non-permit required applications.

In my old house we had 46 outlets in the kitchen.
As if 46 were not enough already, the inspector required that we install 4 more additional outlets in areas we considered to be very hazardous to have outlets at all.
And sure enough, one of the extra duplexes we had to add, became a constant torment to us. Not from usage, its 'required' location was in a place where it was continually damaged and required regular replacement.
Another was in a location where water was splashed on it several times.
But you cannot fight the STUPIDITY of City Hall!

TTUL

I would like to know which municipality or government entity these building
codes (permit charges) are coming from. Category 5e cable is very
inexpensive and the number of telecommunication outlets does not change --
whether daisy-chained or home-run.
Daisy chaining STP cable just introduces potential ground loops, since no

single ground potential point is established (grounding section of NEC and EIA/TIA),

Luckily as long as the contractor does not staple the wire continuous along the studs (just at the "rough-in" plate) .. these nuisances are relatively easy to correct.

Who taught you this physical cabling method? It is also contrary to BICSI certifications.

The National Electrical Code has been changed to reflect the EIA/TIA standards for structured cabling and often takes precedence over local codes, UNLESS the local code is more stringent or specific for fire,health,safety reasons. For example, although ROMEX is permitted under code, DuPage county (IL) as well as city of Chicago strictly forbid its usage for electrical wiring. This stems from tragic fires and safety (e.g. 1959 elementary school fire in Chicago with large loss of life)

Thanks for the link, that was very timely.

I am days away from closing on a second house, where my existing bedroom shop will migrate to.
I've always greatly preferred homerunning everything, even back in my alarm days, in the late 70's.
Much easier to debug, much fewer problems.

I will need to do phones, cable, cat5, and some misc control signals.
I have a wiring panel coming, and a bunch of 66 blocks :)

Brings back the good old days. Some of my resedential alarms filled a 4x8 sheet on the wall, and had dedicated rooms. Doubly or triply redundant systems, with multiple sensing technologies, supervised wiring, phone and wireless reporting. Those were the days.

# 3405. Simple, cheap antenna for portable use.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-10 19:50:39 UTC
From: Graeme <g_frith@bigpond.com>
Message-ID: <41b9fe11$0$25768$5a62ac22@per-qv1-newsreader-01.iinet.net.au>
Source record: 85502

Hi All..
I'm wishing to operate portable from a mountain top location
which has excellent 360 degree unobstructed views, and would be ideal for
the odd weekend of amateur radio operation when I get the chance. Problem
is, there are no trees at that location to use as mounting points for wire
antennas. I'm considering building a vertical antenna using aluminium tubing
that I could telescope together to a height of approx 16 to 17 feet. This
would allow me to tune the antenna to any band between 14MHz and 29MHz by
adjusting the length, and use my cars body as a ground plane. Problem is, I
have no idea how to afix a 16 foot vertical antenna to the top of my little
four cylinder car!
Can anyone suggest a simple way to do this with a minimum cash outlay?
I'd also be interested to hear of other suitable antenna ideas.
I'm very keen to get back on the bands after an absence of several years,
and operation from home is out of the question.

73 de Graeme.....

There's no doubt that many, or most, people could reduce their power by a factor of 10 and still communicate ok. But 10 dB isn't a trivial amount ("only 1-2 S units").

On my Icom 730, a 10 dB reduction will reduce an S9 reading to S6, S7 to S2, or S6 to below S1. Have you tried a 10 dB reduction in signal strength on your receiver and seen how the S meter responds?

If you had 10 dB feedline loss and decided you needed to get it back by increasing your antenna gain, you'd need a 7 element Yagi on a boom considerably longer than 1 wavelength. I can see it now -- an advertisement for a 7 element long-boom beam -- "One to two S-Units gain!"

Good lord..

> Greg
> http://www.schmitzhouse.com/Johns_Electronics_03.htm

nice pix. I'll need to do some cleanup before I can start in earnest, it used to be a rental, and the last tennant left "under duress". Still, it appraises for 20% more than I'm paying. :)
I've been in a large bedroom for about 8 years now, but the bedroom seems to have shrunk over time. That, and I air condition 10 months out of the year, due to the surplus of electric heat from the equipment.

I'm thinking in terms of a 6" pvc into the attic, some of the cables I need to pull thru are nearly an inch in diameter.

I wish I had some from my early days projects, but that would have been kind of a bad idea... Not to mention disallowed in many cases.. The last one I did professionally, was the office of the commander in chief, pacific fleet. Fun doing wiring with an armed marine behind you all day.

There was a time that I put 600 phone lines into a residential basement in wisconsin.

In commercial installs, (multi-story high rises) I used two 4" sleeves
(three sleeves on some of the lower floors) between wiring closets on the
floors.

For residential, I usually use two or three runs of 2 inch schedule 40 PVC
electrical conduit (schedule 80 when required) and one of two runs of 1 inch
PVC conduit. Fits with most stud wall (2x4) construction and 2" is the
largest knockout size for the flush mount enclosures (electrical or
Leviton's SMC)

I keep the RG-6 coax runs in separate conduit from the UTP runs.

I save the 1 inch runs for special marked cables (service runs from outdoor
demarcations, alarm, etc.) OR for fiber optic cabling.

Very good. An equipment listing on the antenna and digital sites and then
he tells us to take a look at QRZ without giving a callsign.

This guy must be from 11 meters.

get a cb antenna (102" whip) then make it longer by putting another whip at the end of it (use a small pipe with a couple of set-screws as a coupling.) - take a warm coat - its probably cold at the mountaintop this time of year.

Thanks to all that replied. I knew it was probably somewhat lossy but
I didn't know it was as bad as has been pointed out. I'll have to
think about feeding it with open wire or twinlead when the weather is
more suitable here in Michigan.

73 and Thanks again.

I didn't mean to imply it was "trival". I have a little 100 watt XCVR that I use moblie and on field day that has a low power (7 watts) setting that I sometimes use to reduce battery drain. The qso total drops, but it is not as drastic as you would think with a 10 dB power reduction. Of course on low power I only go back to the guys with big signals, to make that 10dB seem less of a problem.
I guess that 10 dB loss is all relative to where it is and what would be required to get it back.

Hi Frank, I used one of Reg Edwards Dipole programs to get the line loss. At the time that was the fastest way I could think of to get some numbers. His program lets you describe the antenna, feedline, and frequency of interest and it gives a number of operating conditions including line loss.
As far as where you went wrong? May have been me that was wrong. I think I have TL program somewhere, but don't have time to look at the moment. I checked the impedance of the antenna a couple of ways, and it agrees with your calculation about 300+j700. The difference must be in the way the line loss is calculated?

Reduces problems (you never know who will follow you) with pulling future
RG-6 cables. Also the bend radius tolerances are different. IF UTP cables
are within same pathway the pulling crew has to be more gentle and careful.

Now if you have ever worked a large cabling installation ... you know that
words "gentle" and "careful" are a foreign language terms to many cabling
pulling crews.
Although when I have traveled with these crews .. they referred to the
airline baggage handlers (pre-9/11) as gorillas (former TV ad of a logistics
company).

Thanks, Danny. I'm familiar with the site.
I would like to find out the principle of
the antennas and build one. Don't really
want to buy one.

I understand the basic principle is an open
sleeve design, but the parasitic element
seems to have some sort of series resonant
circuit. That's what I'd like to find out
the details about.

Hi Gary, ok, glad that some of the numbers agree. I used NEC-Win Pro to calculate the antenna input Z.

In real terms there is only 4 dB between our numbers for transmission line loss, so not really a great amount. I am familiar with some of Reg's programs, and have found them in reasonable agreement with other methods, but have not tried his transmission line program.

The fact is, whatever the loss, the use of an open wire transmission line would reduce the losses to near zero -- then he would probably find his tuner could not match it!

73,

Frank

John,

I mostly agree with you, but I have seen a lot worse in these groups,
and you have to give the guy credit for being truthful with his identity.

And just to keep it somewhat on-topic (I can't imagine how to do so with
this many groups), I've used a similar product that I got at Home Depot
(cheaper there), and I was AMAZED at how well it works, exactly the way
that RBR mentioned. When I'm digging around behind my computer, or
amplifier, or my HF rig, looking for the right jack, etc., it it 100x
better than using a lamp or handheld flashlight. I'm farsighted and
have to use glasses for anything closer than 3 feet, and bright light
really helps. Aha! My post is relevent! At least, to other old guys
like me.

Disclaimer: I don't know W7RBR nor anything about his business.

73,
Dave

I agree with Jonesy to a great extent. I am the security guy, amongst other things, at our ISP, so here's my short list on how to keep your PC _YOUR_ PC

1 Don't run a Microsoft OS

2 Don't run a Microsoft OS.

3 If you must run Windows, don't use IE or Outlook (or Express), no exceptions. Eevr. The suggestion on permanently blocking IE with the firewall sounds good, I hadn't heard of that one, but I still wouldn't use IE on anything but a machine with no network connection.

4 See rule #3.

5 No really, reread rule #3. I'm very serious here.

6 If you insist on using Windows use Mozilla, Firefox, Lynx, Opera, or any of the other freeware or open source browsers. For mail use Eudora, already mentioned, or Pegasus, my favotite. I have no knowledge of Agent, so I can't comment.

7 Install a decent antivirus suite, such as McAfee, Norton, Dr Solomon, etc.

8 Install an anti spyware, such as SpyBot etc.

9 Or just don't run a Microsoft OS

All in all, the group is very much right on point on this subject.

> most of what he suggests ( don't under stand the proxy server bit tho).

The proxy server is a bit of hardware or software that sits between
your programs and the rest of the net. If we take the proxy server I use
as an example, (Proxomitron) it will block or allow various things as I
set it. Examples are that it will block pop-ups, nosey Javascripts, and
banners. It also has a list function that will block anything from
certain ip addresses or servers. It can also fake cookies so that some
sites that won't work without cookies will work. Some still won't work,
but noting is perfect.

Its biggest drawback is that it adds some time to the page loading. A
couple seconds or so, except for some pages such as Yahoo, which slow
down a good bit (for a good reason)

> Thanks to everybody tho for their inputs including those you gave a better

PAH! We use our browsers to dl our antenna software and post here in
the group. And this whole thread is helping a member in good standing.
It's near enough to on topic, IMO.

IOW, if someone doesn't like what I'm posting, they are free (and most
strenuously encouraged) to filter me. If they need instructions I will
be most happy to give them some!

I can't contribute a whole lot in this group in the antenna arena, so I
like to help where I can.

I would like to put up a 160 meter loop, fed with 450ohm ladderline.
Although I have enought room, the existing trees would only provide three
supports, pretty much in the shaped of a equalaterral triangle. How well
would a three sided loop work? Should I feed it in the center of one side?

Ed

I see.. I never had to work with multiple different types in one pull.

> Now if you have ever worked a large cabling installation ... you know that
> words "gentle" and "careful" are a foreign language terms to many cabling
> pulling crews.

VBG! Yes, pull till it parts, and then back off a little.

There was this time in the Ala-Moana building, when I was installing coax for video from the first to the 25th floor. We decided to to it from the top down, so somewhere along the way, threading the cables down the core, the end cap came off. A couple floors later, when we went down to take it the next level, we found the raw end sticking inside the cage that surrounds the 440VAC busbars. The other end of the cable was already connected, so that would have been rather exciting on many levels!

> Although when I have traveled with these crews .. they referred to the
> airline baggage handlers (pre-9/11) as gorillas (former TV ad of a
> logistics company).

I saw a UAL baggage handler slam a suitcase down on the belt so hard once, that his feet left the ground. I rarely put anything more damagable than clothes in my bags anymore.

they care, but with the recent budget concerns,they have had other
priorities. Personally, if I were going to build an amp for HF, I'd make
damned sure it had input and output matching and filters (which these units
apparently don't). said filters often do wonders at increasing efficiency
and minimizing interference. still, on 11 meters, the rule is: 4 watts rms
AM and 12 watts PEP sideband, period.

besides, a good antenna can more than make up for a lousy signal (but it
helps to have a clean transmitter and good line).

---

An approximately equilateral trianglular loop, of the same perimeter, will
not work greatly different from an approximately square loop.

The tuner settings will change a little. The radiation pattern will not
noticeably change unless actually measured. Radiating efficiency will be
slightly but not very noticeably less. Connect the feedline wherever it is
convenient. The radiation pattern will change from being crudely
omni-directional to another crudely omni-directional shape.

Reg.

Don't know if you guys in Australia get QST magazine on a regular
basis, but the December issue has plans for a portable vertical that
does 20 through 6 meters, the "FARApole".

See http://www2.arrl.org/qst/

Yes, IE is coded in, but that's because it is integral with the file browsers. I'm running XP Pro.

90% of the time I use Netscape 7.2, which is a step up from 7.1. It has a nice junk mail filter and popup blocker built in. With the browser you can have multiple web sites opened up with only one instance of the browser. The mail and newsgroup section can manage multiple mail servers and news servers. Some of the buttons seem to have gone away, but I found them again as configuration items.

But, where IE is really useful is running it in the FTP mode. I can connect to my web site with a single command and use click and drag to move anything I want to. An incredibly handy little thing. This works with anonymous ftp sites as well. I haven't found Netscape to be interactive with the file browsers.

My mail servers are all spam and virus filtered, so not much gets past them. Netscape then takes care of the rest.

I also use Netscape 7.1 on Unix. It works great on my Ultra-450 running Solaris 8. I have IE on there, but the newest version supported is only 5.1, I think. I run 6.2 here. It works, but not real well. It's a pretty hooky setup.

McAfee runs on both Unix systems and PCs and works very well. You do have to keep up with it. I get a dat file update about once a week. Daily some times, when the hackers are real active. My Unix install scans 20 servers and about 10 TBytes of data in a weeks time. It is not common to find a virus lurking around but when there is one, it finds it. Of course, the only ones it finds are Linux viruses. For this, and many other reasons, I wouldn't recommend Linux to anyone.

But, in the end, I don't have many complaints about XP and IE. I wish IE had a popup blocker like Netscape. The popups do get through, but

I have never had a problem with throwing them away as soon as they pop up. I do highly recommend Netscape. I have found that it renders everything very closely to IE and FireFox. Some minor differences but nothing great.

# 3453. Plotting Package Available for SmartSmith

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-11 14:34:11 UTC
From: w9dmk@crosslink.net
Message-ID: <41bb010c.1431197@news.crosslink.net>
Source record: 85448

The Plotting Package, "NetworkProcessor.zip" is now available - just
point your browser to:

http://www.qsl.net/w9dmk/SWDownloads/NetworkProcessor.zip

This is a small download (45 kB) that you unzip into your present
SmartSmith 1.6.2 application folder.

NetworkProcessor uses a file generated by SmartSmith to capture the
design of you network. It then generates the data to display a plot
versus frequency of any one of the following six variables:
Voltage Magnitude
Voltage Phase Angle
Current Magnitude
Current Phase Angle
Impedance Magnitude
Impedance Phase Angle

Comprehensive Help files (4) included with the executable program.

Source record: 85451

I had to switch from Firefox 1.0 to Mozilla due to a problem in saving
web page content to my local hard drive v-e-r-y s-l-o-w, as in 100%
CPU utilization for 1 to 5 minutes, and sometime hanging (I'm running
XP Pro on this machine, Mandrake 9.2 on the laptop and servers).
Thunderbird has no trouble at all, but when I made the switch, the
pop-ups and banners came in a deluge!

Then I installed Proxomitron with no special settings (I'm still
figuring out its capabilities) and at least 90% of the junk went away.
Three cheers for freeware!

|The Avant browser is really a good one - maybe even better than Mozilla
|Firefox
|- Mosaic, though may not suite your needs.
|but by all means - anything but IE

As I said elsewhere, I use Firebird, predecessor to Firefox.

Unfortunately, some web sites almost demand IE. The attitude is that since 99% of the users are using IE, that's the thing to code for. (I know this because I've had this discussion with my son, who is the IT guru for a nationwide corporation)

I have IRA's at both Schwab and Vanguard. Some of their "features" simply will not work in anything but IE. Threats to move my money to the other guy if they don't fix this fall on deaf ears.

Same with my credit union. For example the login page "moves" three times while loading in Firefox. If I start typing my login info too soon, the boxes move and login fails. Tech support couldn't care less.

But these are the same guys who, although 80% of the users have a dial-up connection, assume that everyone has a personal T1 line to their server and can download their bloated pages instantly.

# 3456. Re: Feeding 30 Mtrs into a 40 Mtr Dipole - Losses ?

You know, Gary, there is another option which no one mentioned. Add a 30M dipole under the 40M job and use the same
feedline. You will likely have to adjust the length of the 40M wire slightly to return the VSWR to the present value,
but you will then have a good antenna for both bands. See any number of references about actual mechanical
construction.

Hi gb

St. Louis County, MO (and several municipalities within same) is who charges additional permit fees for each pull box affixed to the studs or otherwise properly mounted.

The wiring codes are vastly different for residential, commercial, schools, hospitals, etc. I know of NO allowance for Romex in any structure other than residential and even in residential usage, conduit is still required in several areas.

If I recall correctly, regarding Romex A staple is required within 6 inches of a plastic pull box or 14 inches of a clamped metal pull box. Some inspectors (whether code or not) will require a staple on ALL wiring within 6 inches of the pull box, regardless of what kind of wiring it is. Of course, you know how some inspectors are royal PITA's.

It's been over 30 years since I worked my way up the ranks and roughly 10 years since I worked in the field. And even then I only worked in residential. Everything since then was just predication work.

Hi Ed

The IDEAL loop skywire is a perfect circle!

Any deviation from that reduces it's affectiveness, but not very appreciatively that you would notice enough for it to warrant worrying about it.

I've had loop skywires that resembled the letters M, R and even close to the letter V all closed loops of course, and I saw no difference in their performance.

I have no trouble receiving FM radio broadcasts on a small am/fm radio
I sometimes listen to while onboard commercial jet airliners (flying
at cruise altitude), but I never seem to be able to pick up AM radio
stations. It's just static across the AM band.

Any explanation for this?

## 3460. Re: AM radio reception inside passenger planes?

> Any explanation for this?

FM radio generally operates at longer range than AM radio, however it's
limited to line-of-sight. However, when you're 40,000 feet up you can "see"
a lot of transmitters hence the FM signals.

There may be some readers who are not sure what the postings are all about
and why the "Fuss"
.I just linked up to the "BBC "home page which shows their policy
towards"privacy and cookies"
For those who are illiterate with respect to computors and just accept what
is
supplied with the computor as purchased, reviewing the privacy policy
provided
allows the viewer simplified steps to take to protect oneself based on the
browser IN USE.
It does not provide the expertise offered by this knoweledgable group but it
does offer a
preliminary stage of protection by providing step by step computor
instructions to get started
for the illiterate such as I , plus a bit more indepth discussion of what
unknown attachments and cookies
actual do when invading your privacy.
On a side note with respect to some computors slowing down. Are the Windows
based computor programs
with respect to antenna modelling also subject to overload or slowing down
problems or are they some how
immune to the described problems?
Fortunately my program is DOS based so I still enjoy the benefits of the 3
Gig time saver of the processor.
But then..... ignorance could be seen as bliss.

The window holes are much too small to let the much longer wavelengths
of the 'AM' signals through. The body of the plane is a very effective
screen. The 'FM' signals can squeeze in, but it helps if you have a
window seat. I've also listened to SW in the middle of the Atlantic.

Flying from the UK to Florida, on the other side of the Atlantic the
first FM stations you hear are usually speaking French (from Quebec)
It's quite alarming!
Ian.

I reckon you just answered the wrong question !!

The reason A.M. radio can not be received in a plane is that it is a Faraday
cage to the (lower frequency) A.M
frequencies, whereas the VHF frequencies can just about get through the
windows.

There may be a bit of frequency / range issue as well but top band and 80 mtrs
gets across the pond so
I don't think this is the issue here...

Nick

No one has mentioned that in many cases you need the pilot's permission to operate a radio or other electronic device for that matter on a commercial airliner. That includes AM/FM radios.

Radio emissions may screw up the plane's avionics.

See URL:
http://www.fordyce.org/scanning/scanning_info/scan_fly.html

It sez:
"The FAA does not allow inflight use of walkie-talkies, radio controlled toys, AM/FM radios, portable telephones, or portable television sets, all of which may affect aircraft radio and navigation equipment"

Also cruise ships may deny use of two way (FRS) or ham radios -- always check with the communications officer.

For Hams always check with the person in charge on any commercial transportation, busses, taxi's, ships planes etc.

Yeah yeah I know you did it without getting permission, but read the URL as to what airlines have published.

And I know from personal experience that some cruise lines do not allow FRS or ham radios transmissions.

Virgin included the use of radio receivers in their 'permitted list'
about 3 years ago. However, I do wonder about the use of the FM
broadcast band because the LO (tuned freq + 10.7MHz) can land up right
on top of something important in the ATC band.

Hi Mike,

Thanks for your followup posting, and here is Wassup.

I'm not a "NetCop", but instead, an "Elmer". I teach new hams not to stick a fork into the light socket, not to transmit on a dual-band radio on band "B" when you are listening on band "A", and other embarrassing things. I also teach new newsgroup posters that posting an article, and then nearly 30 followups, to an antenna newsgroup, is wrong. It is wrong because people who subscribe to the rec.radio.amateur.antenna newsgroup have a reasonable expectation that postings here will have something to do with ham radio antennas, or at least ham radio, or maybe radio, or at least antennas, or maybe even CB microphones. Not cookies.

With 40,000+ newsgroups out there, there is just no reason to post a generic "help-me" message about Windows XP cookies, into a newsgroup about ham radio antennas. I've been wrong before, but this time, I'm not.

73,
Dave

In this case, it's from the "laundry room" (now equipment room) of a small
2BR house, into the attic of same.

> It's a Real Good Thing to even stuff something like steel wool into
> overly large holes used to pass smallish cable through sill plates.

Oh yes, among other things, the heat bill would eat me alive otherwise.

>> There was a time that I put 600 phone lines into a residential
>> basement in wisconsin.
>
> I think I know the name of that spammer. :-)

Not my site! That site became www.cedar.net
I got the lines put in for free, including running them under a freeway, and
adding a fiber cabinet near the rail line. :)
Our first web server was a SCO box, where I hacked the help system to
respond on port 80.
That was when web server sw was $10k+

>
> Any explanation for this?

Yes, there is. The AM cops have figured you out, since what you are doing is illegal on commercial airliners. The FM cops are a little slower, but they will pull the plug on you also, eventually.

Seriously, though, you are inside a metal cigar tube you call an airplane, and you are being shielded by the body of the aircraft. Although windows (portholes, not Gates), and the metal itself, don't block out signals completely, you will see an effect from this (look up "Faraday Cage" on google). AM broadcast is a very long wavelength (hundreds of meters long) whereas FM broadcast is a smaller wavelength (around 3 meters). If you were trying to throw a bunch of marbles through an upstairs window, you would probably be able to do it. But if you were trying to throw a bunch of beachballs through an upstairs window, it wouldn't be as easy, right?

The aperture is the important issue. Although the airplane is not a completely shielded RF-proof "screen room", it acts somewhat like one. That is why avionics antennas are on the outside of the plane, not inside. That is also why there is a teeny mesh grid in the door of your microwave oven - they have to be that small to block the microwaves.

Using my example before: if you are throwing beachballs (AM broadcast), or marbles (FM broadcast) or a handful of sand (microwaves), how small would you want the window to be in order to block it?

OK, getting back to my first paragraph, if you are ever on a plane with me, please let me know, so I can take the next flight. The local oscillator of FM receivers is often on the same frequency as the VOR stations that airplanes use to naviagate with, and can cause interference. There are failsafe solutions that the pilot has, to deal with loss of VOR coverage, but I don't want to depend on them because you are listening to gangster rap at 32,000 feet. Get an iPod or something.

All the best,
Dave

Dave, we all have been hit one time or another with a computor problem. One time many on this newsgroup got hit with a hiddious virus that upset many so I think you are a bit out of step on this one ,even tho you see your main duty as being a Net Cop.
The fact of the matter is that the main core of premier antenna help contributors all posted on this subject which shows that not only do these members have special expertise with antennas but also have the expertise relative to the computor connection with respect to antennas and the like, and are willing to share with less ability minded people like myself.
Remember the main core of contributors to this group are no lesser an Elmer to that which you pump yourself to be to give you the verbal justification , but I assure you that if a thread unrelated to the primary interests of this group
appeared on a regular basis the initiator would either be ignored or quickly put into his place.
I note that a recent poster stated he was a ham by fraudulent means but apparently you view his thread as more legitamate than mine which is so intertwined and connected to the direction that antennas are moving today and where I am sure you must have posted many times on this particular newsgroup where such programs can be executed ( I assume I have overlooked your antenna contributions) on a $5 Walmart calculator as to make the computor irrelavent to this group.
Since you state that many readers are upset or unhappy with the lack of true antenna
content of this newsgroup now would be the time for an Elmer so proficient as you with respect to what is "right" and what is "wrong" to start a new antenna newsgroup to satisfy the needs of like minded people who are more interested in political correctness than in technical content, of the latter none of which was evident in your posting that only added to the length to the thread without a modicom of antenna content. I think you would have a real hard time in attracting the
groups membership that has such a deep knoweledge and expertise that they are willing to share where the content of their postings must satisfy total political correctness and subject to your absolute rules of what can be written or replied to.
However, if all antenna questions were directed to you for a response you would not have the problem that you ascribe to this newsgroup and amateur radio most certainly would be the beneficiory in your mind of having an alternative.

Let me just assume this is just a consequence of you having a bad day so I can push it all aside
and wish you and your family a happy holiday.
Regards

> something important in the ATC band.
> Ian.
> --
>

Exactly the concern. LO's are used for superhet receivers, and fancier receivers are more computer than analog RF. So now, you have a clock oscillator, with it's harmonics, as another RF source. And don't tell me these emissions are negligible. Receiver (and other electronics manufacturers) sweat blood to reduce those emissions so that they can meet FCC Part 15 (among other) requirements (modest radiation limits at 3 meters distance from the test specimen).

The fact that apertures in the fuselage allow FM frequencies INTO the aircraft, letting you pick them up with the miserably small FM antenna in your receiver, also means that LO leakage from your receiver can get OUT of those same apertures.

You now have the effect of having a small radiation source immediately outside the fuselage, just feet or so from the Avionics antennas. What are the coupling effects? What frequency will your LO land on? Do you feel lucky, punk?

So, in all honesty, YOU can't really say how dangerous operation of an FM receiver will be; but you KNOW that it's potentially harmful.

The advice to ask the PIC (pilot in command) to make allowance for you is just plain dumb. The guy is an aircraft driver, not an expert in RF propagation. He has overall responsibility for getting you to your destination while avoiding legal exposure to himself and the airline. You are asking him to allow a potentially dangerous device to be operated just for your convenience and entertainment. Switch roles for just a minute.

Would YOU allow that? Now switch back. If your PIC would allow it, what else would he be willing to allow or overlook?

While I will admit that aircraft disasters are rarely caused by a single factor, it's just plain dumb to add risks that you don't need to take. I want pilots who are conservative, who do a thorough pre-flight walk-around even when it's raining, and who will enforce rational rules on self-centered, ignorant passengers. Can't you put your electronic life on hold for a few hours? Whatever happened to reading a book, or just looking out the window?

# 3472. Strange question about SWR on HV lines

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-11 22:33:22 UTC
From: ON5MJ <my_call_sign@skynet.be>
Message-ID: <41bb7597$0$7822$ba620e4c@news.skynet.be>
Source record: 85469

Hi there,

A friend of mine asks what happens on high voltage distribution lines about SWR at the distribution frequency (50/60 Hz). I'm stuck.

I understand that HV generators/transformers behave like voltage sources and not power sources. This means that conjugate impedances don't apply here but what about the existence of SWR on those kind of lines and the possible consequences on very long lines.

Anyone has an idea ?

73 de ON5MJ - Jacques.

Unlike DOS, Windows is a multi-tasking environment. Therefore, if you have many programs running at once, each will run slower. (You can, if you want, apportion the CPU time unequally among them.) However, as far as I can tell, the total time it takes for all of them to do their calculations isn't inherently slower with Windows than DOS. Windows-based antenna simulation programs are no different than other Windows applications.

When running in "DOS mode" (under Windows systems prior to XP -- it's not available in XP), you are running in a true, single-tasking DOS environment. This is the mode you have to boot separately into when starting the computer. But if you choose the "DOS prompt" (or "command prompt") while running Windows, you're really running in the full Windows environment, and emulating DOS as just another Windows task. Programs running in this mode can't run any faster than a normal, native Windows program, since they're also subject to the time sharing of the multi-tasking system. There might actually be some additional overhead from the emulation process.

The first Windows version of EZNEC, v. 3.0, ran calculations about 20% faster than the DOS version, possibly due to a compiler change. There was certainly no major slowing down of the calculations due to the different operating system. The current version of EZNEC, v. 4.0, runs up to several *times* faster than that due to code changes.

Part 91 GENERAL OPERATING AND FLIGHT RULES
Subpart A--General

FAA Regulations Sec. 91.21

Portable electronic devices.

(a) Except as provided in paragraph (b) of this section, no person may operate, nor may any operator or pilot in command of an aircraft allow the operation of, any portable electronic device on any of the following U.S.-registered civil aircraft:
(1) Aircraft operated by a holder of an air carrier operating certificate or an operating certificate; or
(2) Any other aircraft while it is operated under IFR.
(b) Paragraph (a) of this section does not apply to--
(1) Portable voice recorders;
(2) Hearing aids;
(3) Heart pacemakers;
(4) Electric shavers; or
(5) Any other portable electronic device that the operator of the aircraft has determined will not cause interference with the navigation or communication system of the aircraft on which it is to be used.
(c) In the case of an aircraft operated by a holder of an air carrier operating certificate or an operating certificate, the determination required by paragraph (b)(5) of this section shall be made by that operator of the aircraft on which the particular device is to be used. In the case of other
aircraft, the determination may be made by the pilot in command or other operator of the aircraft.
---

Seems to me the pilot ought to know.

Roy
Believe it or not I understand what you have posted so the info you have
provided will be good news to antenna modelers.
I really do not know how my personal antenna program works except I have a
small disc inserted that when I start the computor I have to press the F12
key when prompted and somehow it does not display the normal windows entry
but
goes straight into a DOS managed antenna modeler program. I suspect that the
disc somehow partitions the Dos emulator from the windows program and makes
it a seperate entity in a similar way that previous widows programs did
before they were bundled together.When I model closely coupled antenna
elements designs where one has to make it 80 segments a shot a slow down of
the coprocessor would be unacceptable

FYI, I have IE6, with Service Pack 2 (for XP Home Edition), and that
includes a Microsoft pop-up blocker. It works better than StopZilla's
blocker, and it's free.

Hi Jacques, A 60 HZ power grid has generators, loads and matching devices,
just like your Ham rig. The generators have step-up transformers, and at your
home you have step-down transformers, which are impedance matching devices.
Just like your Ham rig doesn't like working into a reactive or mismatched
load, neither does the power company. In the case of a reactive load the power
company switches in capacitors to compensate. Capacitors are used due to the
inductive load produced by the multitude of induction motors out there.
If your Ham transmission line operates into a mismatch, you have a high VSWR,
same thing with the power company. The power company has to compensate or lots
of people will be sitting in a cold dark house. You have matching problems
whether you are operating at 60 HZ, or 14 MHZ.

Hi Ed,

This would make sense (to switch roles) if the administration hadn't
trumped that call. Reports recently indicate that the FAA may soon
allow anyone, anytime, to make cell phone calls while in flight.

Anything goes for a price. The FDA has proven that it is no longer
the watchdog of medicine, and the FCC is the gateway for spectrum
bargains and marketplace sweeps.

With these acronyms, one may well wonder what the "F" stands for.

What a load of horse shit.

You guys are acting as if the engines and flight control surfaces of an aircraft are intimately tied to the plane's radio receiver, and the slightest odd or out-of-place signal that it receives is enough to send any plane into a tail spin.

All this while the air travel industry is considering allowing passengers to use their own cell phones WHILE THE PLANES ARE IN FLIGHT by adding cell-phone relay stations to the planes and allowing any such calls to be completed via satellite. So I guess the feeble radiation by my FM radio (powered by 2 AAA batteries) is enough to cause a plane to dive into the ocean, but the guy next to me putting out 3 watts of near-microwave energy is totally safe.

What about my hand-held GPS unit? Any chance me using it (during all phases of a flight, which I do routinely) will result in a one-way ticket to kingdom come?

Getting back to the original question (poor to non-existant AM reception), I understand the idea of aperature and long wavelenths of AM radio and the size of airplane windows - but what about the effect of ALL the windows on a plane? Don't they create a much larger effective apperature when you consider all of them? And since the plane isin't grounded, isin't the exterior shell of a plane essentially transparent to all RF (ie it's just a re-radiator) because it's not at ground potential?

Hi Jacques,

You should have stopped right there because the rest of your
statements were crowding into the province of old wive's tales.

When Hoover Dam was put into commission delivering Power to Los
Angeles, the distance was far enough to observe the effects of SWR -
in exactly the same manner we observe them on lines at HF, or VHF etc.

The notion of "Matching" was born in the AC Power industry.

This becomes a matter of the distance between them and the phase separation at any wavelength. What you describe is a common technique for coupling power between waveguides (in what are called directional couplers). However, this is not the same thing as accumulating and enlarging an opening because such couplers will add energy in one direction, and subtract it in the other (which makes for their directionality).

> And since the
>plane isin't grounded, isin't the exterior shell of a plane

>it's not at ground potential?

Ground does not always mean "at one with the dirt and rocks." At one time it did, when cowboys put up talking wires, and indians pulled them down. Ground has since come to mean "common" (which when you think of it, brings us back to dirt, metaphorically). Common means that everything is at the same potential. If there is no potential difference, then there is no way to measure a voltage based signal. In other words, it's a massive short circuit, and the only way to sense a signal is to inductively couple to the short circuit current.

This takes us to the second killer courtesy of physics. High frequency current travels on the surface of smallest, positive radius. AM frequency qualifies here in spades, even though it is conventionally called not HF but MF (even VLF qualifies as High Frequency in this context). The aircraft frame thus presents both curvature and radius such that the current confines itself to the outside of the shell with an inclination for the narrow wings and tail section, rather than the elongated body.

You might be tempted to inductively tap into this frame current, but then you are on the negative, inside radius of the current carrier (makes the tube interior self-shielding). Whatever current is flowing, is on the outside of the skin, not the inside - that is, until we consider skin depth and penetration. But then it appears that experience described here suggests that not much of that frame

current penetrates inside.

Too bad it's not that simple. But if you're really into this kind of argument, do a groups.google.com search of the sci.geo.satellite-nav newsgroup. There you'll find endless argument, speculation, and rationalization ranging from well informed to completely clueless. There's surely more than ample ruminating there to satisfy anyone, regardless of your orientation or clue level; it's surely not necessary to do it all over again here.

A bit larger, yes. But the attenuation inside is still very high, since the windows are extremely small and spaced very close, in terms of wavelength. Sort of like the screen of a screen room.

> And since the
> plane isin't grounded, isin't the exterior shell of a plane
> essentially transparent to all RF (ie it's just a re-radiator) because
> it's not at ground potential?

No, being at "ground potential" plays no part in shielding. Currents and fields on the outside aren't magically allowed to violate basic laws of

physics and migrate through a good conductor just because a shield isn't at "ground potential". For that matter, a box that is at "ground potential" at the bottom is nowhere near that potential a quarter wavelength up the side. No shield over a small fraction of a wavelength on a side could work if "ground potential" were a requirement. Yet room-sized shielded enclosures are routinely used into the microwave region. Try your own experiment. Turn your portable radio on, turn up the volume, put it into a sealed can, set it on a stool, and see how much you hear.

Well you have been referred to the FAA Regs and the Airline policies and
ignored them.

http://www.fordyce.org/scanning/scanning_info/scan_fly.html

http://www.airweb.faa.gov/Regulatory_and_Guidance_Library/rgFAR.nsf/MainFrame?OpenFrameSet
Section 91.21
---
So here is another URL we hope you read about GPS
http://gpsinformation.net/airgps/gpsrfi.htm

Just a snip:
There are documented cases of AM/FM radios causing interference with Avionic
systems and as a result, AM/FM radio receivers are generally prohibited.

You will be happy to learn of this quote;
"By design, (or happy accident), the "spurs" generated by a GPS generally
fall outside the communications frequencies used by Aircraft and so have not
been a problem even though a few "spurs" exist.
But SOME airlines do not permit the use of GPS receivers. Why is that if
they are "safe"?"

You will be unhappy with the answers. Hope you go to the URL for the answers

Here is one:
If a GPS is safe, why can't I use it on an airplane anyway, even if the
pilot says NO?
Answer:
This would be a) unwise, b) illegal and c) dangerous. Never presume that
you have more authority than the Captain of a ship! He is responsible for
the lives of his passengers and likely has knowledge and experience about
his aircraft and/or equipment and/or this particular flight that no one else
has.. The use of a GPS by a passenger is NOT worth a confrontation and a
possible visitation from the police or FBI when you land..

READ THE LAST SENTENCE AGAIN

Be safe, obey the law, stop guessing -- get educated and read these URL's

ed,
it isn't hard at all. in fact, I can also be an ass if I really try hard.
most of the time though, its a simple matter of:
1. forgeries
2. someones buttons getting pushed a little too frequently
3. other personal "considerations"
4. just venting.

all in all though, it seems to me that some folks just have a harder time
trying to get along than others.

my $0.02 worth.

I don't understand the "voltage source not power source" stuff. AC generators on a grid are certainly both.

Impedance matching a generator to the load would be a bad idea, as it would result in losses internal to the generator equal to the delivered power. In the case of a generator near to my heart, that would be half a gigawatt. (Actual losses are in the megawatt range.)

I haven't heard of SWR being a consideration on a power transmission line. A wavelength at 60 Hz is about 3,000 miles, if I did the math right. There's certainly that much interconnected grid in the USA, but the system is distributed. It's like a big bus with hundreds of generators spread along it, along with even more load connections. Each station generates in phase with the voltage that happens to be present at its location.

I suppose if you had an isolated generator hundreds (or thousands) of miles from its load, standing waves would exist. I'm not sure how (or if) they would be counteracted.

I also have IE6, but I run XP Pro with Service Pack 2. I have not found that the Microsoft pop-up blocker is better. I hit a site, a couple of months ago. Before I connected, my counter was around 900 popups blocked. The next time I looked at it, it was 9,000 popups blocked. I didn't even notice a glitch. This was with Netscape. With IE, I would not have been so lucky.

IE has a lot of good points and is the most used browser. I develop my web pages using Netscape, but wouldn't publish any of them if I didn't first test them with IE. I run a monitor on my web site and IE has a 80 percent share of all browsers, but it is also the most targeted. Netscape is only running at 10-12 percent share, with all the rest filling in the last 8 percent.

Netscape is also free.

Good point. I have used fiberglass insulation for both minimizing heat loss
and for some firestopping, however you can purchase from many electrical
contractors .. firestopping putty
(it was a red colored putty when I used it 12 years ago)

Given that the aircraft voice comms are just above the FM BCB, and the typical first IF is 10.7 MHz, it's not too hard to imagine the LO sitting right on the tower comm frequency.
You may only radiate a microwatt, but you're much closer to that antenna on the aircraft than the tower is. Inverse square law makes it very easy for you to win that contest.

This is a pointless argument though. It's a health and safety issue, and you either follow the airline's rules, or I hope they boot you off the plane (optionally, landing first for your convenience) It is just that simple.

For residental yes, but I am seeing less of it even in residental.
Much more usage of flexible or rigid conduits ..
although metal vs PVC / composites is a religous war in many areas.

> If I recall correctly, regarding Romex A staple is required within 6

So in the case of an airline (air carrier) the airline makes the
determination to allow, NOT the pilot.
In a private plane, the pilot can decide to allow.

No, you need to accept the blame for that. At one point you thought it was
funny to use someone else's call, and even made it a point to perpetuate it.
Don't now attempt to make yourself appear less than culpable.

Indeed. Steel wool burns rather nicely, once started.

Hi Nick,

Phase is necessarily found in Impedance. As you allow that multiple
generators share a line, they are also across the load as a load if
they do not present the right phase.

As for the "bad idea" of matching, you are appealing to Edison's old
and deliberate misreading of Thevenin. Matching does NOT require a
resistance, this is a mis-read of conjugate matching that follows the
fact (in antennas). It does not drive the need (in power delivery).
Power stations only need perform a Z Match, not a Conjugate Match.
Any form of X is sufficient to accomplish the task and they do it far
simpler through field excitation control.

Back when Edison was battling Westinghouse/Tesla in the DC vs. AC
distribution system wars; Edison tried to confuse the issue with his
munged up version of Thevenin's Theorem insisting that his competitors
would have to burn up half their power to deliver half their power.
He thus claimed his DC system to be more "efficient." New York
bankers didn't know the difference between Thevenin or Copernicus. In
fact, it was Thevenin's proof that crippled Edison in the marketplace.
The only way to cut losses was to lift potentials into the
stratosphere. Edison also had a campaign trying to prove AC was
lethal, but DC was survivable (largely true). But with a low loss
system running in the KV and no way to convert it to residential use,
the writing (about lethality) was on the wall. AC, on the other hand,
could deal with that easily.

Edison's business/technical logic would have to wait for nearly 100
years to be resurrected for the ENRON bubble to coincide with New York
banker IQ phasing.

Richard Clark wrote:
"---the distance was far enough to observe the effects of SWR - in exactly the same manner we observe them at HF or VHF etc."

Yes, that was anticipated.

The wavelength is a little less than 186,000 miles per second divided by 60 cycles per second, or 3100 miles per cycle approximately. The reduction in wavelength is due to the velocity factor of the transmission line. Construction determines the velocity factor.

The phase delay ib transmission over the actual distance between Hoover Dam near Las Vegas and Los Angeles is only a few degrees. For example, a 60 Hz transmission line slectrical length of 310 miles would be 1/10 wavelength or about 36 degrees. Surely noticible but not crippling.

Now, many high-voltage transmission lines are transporting d-c. The rule of thumb is that you need a kilovolt per mile of trangmission line length to get efficiency. So, hundreds of miles require hundreds of KV. At these voltages, the difference between rms and peak voltage becomes important. RMS = DC. Now, conveersion from a-c to d-c and back again is fairly easy and efficient. So, we have HV, DC power transmission. Tesla had the first laugh. Now, maybe Edison has the last laugh after a hundred years of development.

Best regards, Richard Harrison, KB5WZI

Thanks for the idea George, I hadn't thought of that one. I knew the
30M into the 40 dipole wasn't the best in the world as I didn't hear
the signals on 30 that I would expect to hear but I didn't know it was
as lossy as pointed out. I'll have to give it a go this spring or
summer.

I had never thought of the power industry having "matching" problems
until I picked up a magazine ( the New Yorker of all things ) in a
doctor's office years ago and there was a story about fluctuating
SWR's etc and what the power company did to compensate. Unfortunately
I got called in to see the Doc before I could finish the article.
Thanks for sharing some light on the subject.

I found a bug in the Plotting Package. Anyone who has already
downloaded it should return to the site and download

http://www.qsl.net/w9dmk/SWDownloads/NetworkProcessor2.zip

It's a small download of about 45 kB and is to be unzipped in the same
application folder as SmartSmith 1.6.3

Thanks,

Bob, W9DMK, Dahlgren, VA

A couple of ideas....

Mount one of those 'ski bar' roof racks on your car and clamp the antenna
mounting onto that.

If your car has a tow bar fitted, you can use this as a great mounting
point for a short tower made from telescoping metal tube, and string a
long wire or sloper dipole from that (in the form of an inverted V). Use a
tent pole with 2 guy ropes at the outer ends of the antenna. All these
bits should fit easily into the boot of the car.

Have fun, and be careful of those thunderstorms when your on top of the
hill!

Pip

Hi Richard,

Actually, the ironic testament to power distribution (back then, 100 years ago) was found in Italy where they had a wire rope pulley system 20 miles long that was over 90% efficient.

The VERY first thing to remember about power transmission is that generators must NOT be conjugate matched to loads.

We CANNOT have half the power dissipated in the generator!

Virgin is a British Airline, so they can permit the operation of radios
once the plane leaves US airspace. Once the plane leaves US
airspace, it is no longer subject to FAA regulations.

Thank you gentlemen for all your replies,

To make a summary:

The discussion with my friend started about the difficulty in Sweden to sell electricity to continental Europe due to long haul lines and supposedly SWR on those lines. I didn't understand this last point.

Before questioning you, my thinking was (back from the university 30 years ago but a bit confused now)

1. generators on high voltage lines are "voltage source" rather than "power source" because the purpose of electricity transportation is to deliver a voltage to users which is as stable as possible. That is the definition of a voltage source. If the purpose would be to deliver the maximum of power (I mean to be a "power source" = gives a power as stable as possible) the power dissipated in the generator would be the same than the one delivered to the loads. By definition, loads vary all the time but voltage must not vary accordingly. RF amplifiers are power sources, electricity distribution uses voltage sources instead.

2. Following the definition, SWR is the ratio between load impedance to line impedance. In grids, loads are low impedance and transmission lines are high impedance. This means that SWR must be very high in any case for grids.

3. Being a voltage source, a HV generator doesn't need (even must not) to be conjugate matched to the line, only the reactance must be canceled. Reactive power at the load is theoratically not paying load as this power is not real power at the generator but reactive load contributes to encrease line current (not in phase of course). As an encrease of line current contributes to voltage loss on the line, this contributes to line power loss and this is paying load. This is why reactive load must be avoided and canceled by capacitors (because loads are usually inductive).

Now this doesn't explain what is the effect of SWR on grids.

So I would like to question some people replying to me:

1. W3RV - "I understand that excessive SWRs on the long-haul transmission lines have brought entire grids down"

Do you have an idea why it happened ?

2. KB5WZI - "Now, many high-voltage transmission lines are transporting d-c.". - "... the difference between rms and peak voltage becomes important. RMS = DC."

I am not that aware of this but it makes sense that efficiency of AC/DC + DC/AC conversion must be higher than the one of pure AC transmission. Can you explain the difference between RMS and peak voltage in this case ?

73 de ON5MJ - Jacques.

The following details will give you some idea of what you are waffling
about.

A 2-WIRE, WIDE-SPACED, POWER TRANSMISSION LINE.

At a frequency of 60 Hz

Length = 100 miles.
Wire diameter = 1 inch.
Wire spacing = 10 feet.

Nominal RF Zo = 650 ohms.
Actual Zo at 60 Hz = 650 ohms.
Angle of Zo = -2.6 degrees.

Velocity factor = 0.99
1/4-wavelength = 767 miles.
Resonant Q at 60 Hz = 11

Inductance = 3.54 milli-henrys per mile.
Capacitance = 0.00836 micro-farads per mile.

FOR A LOAD OF 500 OHMS -

Input impedance = 520 + j*51
Line loss = 0.1 dB.
Power Loss in line = An economical 2.3 percent.

Reflection coefficient = 0.133
Angle of reflection coefficient = 170 degrees.
VSWR = 10.5

Economics rules the roost at power frequencies.

The normal transmission voltage on such a line is measured in terms of
100,000 volts.

Note that, with a resonant Q of 11, should an open-circuit fault occur at a
distance of 1/4-wavelength the voltage at the fault can rise to a million
volts or more. Electrical power engineers have far worse problems than mere
radio engineers have on the popular 40m band. They too are concerned with
reflection coefficients and SWR. ;o)

But the technicalities were all exactly sorted out in the Victorian age by
the young, self-educated, recluse and hard-of-hearing genius like
eethoven - Oliver Heaviside who was derided by the old-wives and silly guru
university professors of his age.

The above technical details, and more, can be computed and studied, from power frequencies up to UHF, by downloading, practical, easy-to-use programs RJELINE2 or 3 from the following website. Download in a few seconds, not zipped-up, and run immediately under common-or-garden DOS/Windows.

The fact that the terminal voltage on a power line can be higher than
the sending voltage has been known for a very long time. Google for the
'Ferranti Effect'.

That is what it says

But the average passenger wouldn't know the airline policies.
If so informed with written material, most won't read them anyway.

The pilot and flight attendants should know-- so asking is the reasonable
thing to do.

I queried several Airline pilots I know and they were all aware of their
Airline policies and stated they can't give permission but could state the
Airline policies and do so. AM/FM radios, GPS, FRS, GMRS, cell phones, Ham
radios and other devices were included as no no's on their Airlines.

Also Flight attendants are alerted to instruct passengers not to use certain
portable electronic devices so listed in their airline policies.

Yeah I know we are beating this thread to pieces, but maybe some readers
will desist in using a $10 Chinese radio that spews RFI all over the
aircraft.

Yes there is room for technical argument as how dangerous some devices are.
But the airlines have made their decisions based on the FAA regs.

Case closed

|Given that the aircraft voice comms are just above the FM BCB, and the
|typical first IF is 10.7 MHz, it's not too hard to imagine the LO sitting
|right on the tower comm frequency.
|You may only radiate a microwatt, but you're much closer to that antenna on
|the aircraft than the tower is. Inverse square law makes it very easy for
|you to win that contest.

Correct. Let me offer a slightly different but illustrative example.

Since this is cross-posted to some non-ham groups, bear with me. In
the 1960's I operated my amateur station on the two-meter (144 MHz)
band using several hundred watts of AM and directional antennas.

I'm in Tucson where we have both a commercial airport and D-M AFB. An
acquaintance of mine, also a ham, was the FAA tower chief at Tucson
International.

One day he calls me on the phone and says that the tower guys at D-M,
knowing he was a ham, called him first rather than the FCC, to report
that I was interfering with their tower communications.

To make an involved detective story short, it turned out that another
ham, who lived just outside the AFB was using a Heathkit "Twoer". The
Twoer used a super-regenerative receiver and was picking up my signal
and re-radiating it on the tower frequencies. I was getting blamed
for the other guy's illegal transmissions.

Considering that this technology is probably used in more receivers
today than any other type (garage door openers, computer wireless
links, etc.) if I'm flying, I hope they are all turned off.

|
|This is a pointless argument though. It's a health and safety issue, and
|you either follow the airline's rules, or I hope they boot you off the plane
|(optionally, landing first for your convenience) It is just that simple.
|

Typical ass hole! Yep, we'll see you on 28 MHz and one day soon, perhaps in the FCCs list of those busted for $7 grand - too! Then we'll see who laughs hardest. You know the old saying, those who laugh last, laugh hardest.

I hope I DO hear you. I would love to be the one to be involved in busting your ass. So, go for it! Talk away. The more you talk, the better chances we'll bust your ass. As for being stuck up, yep... it will be your amp - up your ass. You think you'll get away with it. Truth is, illegal ops stand out like sore thumbs. VERY EASY to spot. AND FIND. Times a ticking - boy.

This will change! Where I work, we have been told to abandon Internet Exploder. I already had years ago as part of UALMPAP (usa as little Microsoft product as possible)

Between Students and Employees, that is probably only about 100,000 people. Since it is happening elsewhere too, it *will make at least some dent.

Of course, you only threatened. If you actually moved the money, and gave them that as a reason, they might start to pay attention

> Same with my credit union. For example the login page "moves" three

As long as you still use them, they won't care.

A few years ago, I started seeing a lot of websites that had incredibly superflous Junk on their intro pages. An example is once I needed a ne pair of skates, and I needed them quick. I wnet to the makers web pages, and the first thing it tells me is that I need to download a plug-in in order to see their site. So I download it. Then it tells me I have to restart my computer, which is a little bit of a pain. Then it bombs my computer, then after rebooting and waiting for scandisk to check and repair it, I finally get to the site again, I get to see the critical software advance that I couldn't access their site without. It was a freakin' movie of a goalie sliding across the ice! I called them and told them that I wasn't going to buy any more of their skates and told them why. 400 bucks lost for them, actually more like 800 bucks, since I was often buying skates for my kid at that time.

BTW, they ended up changing the site eventually.

Art,

There was nothing wrong with your posting. It's just in the wrong
newsgroup. I don't know how to make any more simple.

All the best, and good luck with your "cumputor",
Dave

Hey folks, let's not overdo the safety aspects here, so no one panics if aboard an airliner and sees someone using a radio. I doubt any device emitting small RF will be able to make comm reception unreadable. Even if it did, there are then fallback procedures which the pilot is required to know by heart, and the pilot is even permitted to continue flight all the way to the gate without any communication at all. Believe it or not, other aircraft may not have to be vectored out of your way, or even informed about your problem. But in reality, the pilot would simply peek at the coffee-stained nav chart and dial up another controller on another freq and ATC will say another frequency to come up on, or "stay with me."

For navigation on frequencies 108.00-117.95, besides being rather strong signals, the nature of the modulation is such that interference would have to be strong and be just so, to cause navigational error. More likely there would a panel indication of an unusable signal -- because the receiver must be designed this way, and the pilot can listen to the nav audio to hear the problem. The aircraft is also in radar contact, so that if the pilot were to wander off course -- you're allowed a fairly wide margin -- ATC tells you if outside the margin or not following a clearance if given a "direct." If you can't rectify it, you simply ask for radar vectors, or switch to GPS nav, or vice versa, or clearance to go direct to another nav beacon off the nose, or GPS direct if equipped.

Now the same considerations apply to flying the approach and landing, but the pilot would rather not have to deal with potential interference to either nav or comm, especially if the airport is 1/2 mile visibility in fog. Thus, it's not too uncommon for the pilot to grant permission to use a radio device only while in cruise.

Also, ATC will be able to tell the pilot that other aircraft are not reporting a problem, a hint of possible interference from inside the cabin. But has anybody ever heard a cabin announcement during flight to turn off any devices?

Fred F.

Everything you have written is probably correct BUT
That is not the point -- The FAA and Airlines have regs and policies about
portable electronic equipment aboard an airliner PERIOD

And yes a sharp flight attendent did tell me to turn off a GPS unit.

Fred,

Nearly all aircraft accidents are caused by a series of unlikely events all happening together, none of which by itself would be a problem.

Would you want to add one more "unlikely event" to your next flight? Do you have life insurance?

73,
Dave

(to keep this on topic, I will say this: last week my garage door snagged the corona tip on my ATAS-120 and broke something inside the tuning section, and bent my trunk lid. A $300 mistake. Damn.)

Our club repeater also ended up interfering with the local tower.

It seems that the transmitter PLL was unstable, and "hopping" between that frequency, and ours.
We were clearly audible in their recordings.

Lest any "experts" step in and claim that you can't receive FM on an AM receiver, I'd ask them to consider what effect the passband filter of the AM receiver's IF might have on the FM signal as it deviates from side to side....

I hit the magic codes and took the repeater down, once we determined that this was indeed the source.

A re-tweak of the transmit PLL, and a stub filter cut to pass 146.730 and reject the tower frequency, cured the problem, and insured that if it ever happens again, they probably won't hear us. The tower now has our phone numbers in their books, in case there is ever another problem. The tower complimented our rapid and assertive handling of the problem in their closing letter to the FCC.

Repeater cans don't do much for signals that are far out of band.

Hi gb

>OK, that helps ... they should know better .. especially with Emerson
>Electric in town and that I believe the IBEW started in St. Louis !

It was hard working in St. Louis, we have so many larger companies and
unions controlling the government, that the smaller companies have
virtually no chance of getting ahead.

>For residental yes, but I am seeing less of it even in residental.
>Much more usage of flexible or rigid conduits ..
>although metal vs PVC / composites is a religous war in many areas.

I still prefer metal myself for indoor, PVC for exposed outdoor and
underground installations.
I often use conduit even when not called for, especially in attic runs
where squirrels, etc. might some day be able to get to the wiring.
But within the closed cavity of partition walls, I see no need for
conduit, unless you are considering future additions using same.

>Yup, worked under one for while as summer job. Made me a damn
>perfectionist. Very difficult to buy a house these days (better to close my
>eyes)
Ain't that the truth!

>It's interesting that since WW2 how the amount of electrical appliances,
>computer, etc. in residential and SOHO (small home offices) .. that they are
>looking more like commercial every decade !

That's one of the reasons for so many outlets in my last home!

You may laugh at this, considering it's simple residential wiring.
But every bathroom and/or windowless room that I wired, I ran two
separate lighting branch circuits to each room(s).
If a bathroom had both ceiling lights and vanity lighting, they were
wired on separate branch circuits, so one would not be left in the
dark if one of the breakers was tripped.
Same with long hallways, every other ceiling fixture was on a separate
circuit.

I think I use more electric in my home/office alone than I do in all
the rest of the house, including the kitchen.
Color laser printers and copiers are all on dedicated circuits.
Computers are on their own dedicated circuits, then all the peripheral
components, scanners, hard drives, USB powered ports, etc. all on
another separate circuit.

The nightmare comes in trying to keep both sides of the bus balanced while keeping spikes from large motors all on one side and away from the computers.

Start at an extreme case for the T. If the two conductors of the T's stem are close together, then your T loop's stem is going to act like open feedline. If the two conductors of the T's top are close together, then your T loop's top is going to act a folded dipole.

Opening parellel sides of the stem or/and the top makes the structure move towards becoming a square (rectangular) assembly.

If you keep the lower end of the stem close together and widen the top of the stem, then the T moves towards an inverted delta assembly.

Ouch. That'd be categorized as a "double-plus ungood" for certain!

I believe the magic words are "slope detection". The resulting audio
on the AM receiver isn't great (it's often distorted) but it's
certainly there.

[Dramatic generalization mode off]

Nice sweeping piece of dis-information there buddy.

How about this: Nearly all aircraft accidents are caused by a single failure in a single component or a single failure to do something. Pitot tubes that are taped over. Fuel tanks that explode. Structural failure that causes entire pieces of fuselage to peel off while in flight. Fuel leaks that turn large jets into gliders. Cabin fires caused by the overload of a single wire powering the entertainment system. Air pressure equalization valves that bleed cabin air rendering the occupants unconscious and results in a ghost plane flying thousands of miles before crashing. Failure to de-ice. Overloading resulting in stalling upon take-off. Failure to secure cargo upon takeoff. Being struck in the fuel tank by a piece of debris on the runway kicked up by the tires. An engine ingesting a flock of birds. A shipment of improperly-disarmed oxygen generators placed in the cargo hold. Lack of proper lubrication of tail jack-screws. Tail fins that are not as strongly connected to the fuselage as they should be. Need I continue?

A series of events will surely happen AFTER any of those incidents, none of which are either unlikely or unexpected, and by and large would have no effect on the outcome.

Will the in-flight use of an FM radio EVER cause a plane to run out of fuel? Or cause a sudden ice build-up on the wings? Or blow out a tire upon landing? Or an overload of the electrical system leading to a fire? Will the feeble RF emitted by the LO even be detectable OUTSIDE the plane, where the plane's antennas are located?

If you read the various documents on the web relating to issues of in-flight use of PED's (personal electronic devices) it's clear that

1) The FAA and NTSB are either negligent or a bunch of cowards for not forcing the AIRCRAFT MANUFACTURERS to determine the level of susceptibility of their planes to PED's. Instead the issue is pawned off to the aircraft operators when logically it should be the airplane makers!

2) The use of cell phones (analog and perhaps more frequently GSM) seems to have the most influence of any PED. The next most frequent culprit seems to be laptop computers.

3) No incidence of communication failure or disruption seems to have ever been documented by a passenger's FM radio receiver.

4) MANY MANY incidences of navigation equipment errors caused by improper installation / connection of the equipment, or interference caused by one of the plane's other systems where these were first attributed to a PED.

5) Planes have to fly near high-power commercial radio and TV transmission towers. They fly through the beams of powerful radar signals. They get struck by lightning. There are those that say that for a (commercial jet) to be certified there is no way that a certified plane could be susceptible to the stray RF given off by PED's (at least PED's that are non-intentional radiators).

6) The authorities would probably not admit it, but the ban or restrictions on PED use in planes probably has more to do with insurance/liability reasons, or passenger distraction reasons, than it does for technical (interference) reasons.

PED's are here to stay. There will be more of them, and people will use them wherever they are. It makes just as much sense to ban them or perform half-ass on-board supervision on a plane for these devices as it is to ban them from cars. PED's used cars cause injury and death each year (due to driver in-attention). Instead of banning radios, phones, and entertainment systems in cars, they instead come from the factory with them installed! Where's your crusade against that situation? Where are your dire warnings here?

> Would you want to add one more "unlikely event" to your next
> flight?

Nothing caused by or brought on board by a passenger (short of alcohol, a gun, a bomb, or otherwise a strong intent to do harm) will or has ever caused anything bad to happen on a plane or to a plane. No gun ever brought on board (and there have been MANY!) has ever discharged. No can of hairspray has ever exploded in the cargo hold.

There is relatively little variety in the types, makes or models of commercial airplanes flying today. There is a high degree of uniformity in construction of these vehicles. There have been millions of flights over the past, say 20 years. There have been many hundred million passengers carried by these planes. There surely has been ample opportunity for all sorts of PED's to be used on these planes (surreptitiously or with consent). If any particular plane model (or even specific plane) had a systemic or inherent susceptibility to a PED, it would have been recognized by now.

Gain (in one direction) means nulls (in other directions)
if you want gain - then you should specify 'in which direction' - and
proceed from there, keeping in mind a different type of antenna may be a
better solution.

sounds like a folded dipole. - and it should act like one too.
you'll find that if you can move the 'vertical' part of the 'T' (feedpoint)
using a pully setup, that the arrangement can be used for several bands.
put a 4-1 balun at the bottom of the T.

What is a Pitot tube anyway? I have seen a switch for most aircraft
in Flight Simulator marked "Pitot Heat", what is that?

I'll bet there's no record of a U.S. airline accident caused by faulty navigation equipment for any reason, or at least excluding maybe the early years. General aviation, yes.

> Would you want to add one more "unlikely event" to your next
flight?

I have no problem with any airline with a flat "no" policy on this, because things do happen even if rarely. NASA gathers the PED incident data, and over a 14-year period, there have been less than 100 events, mostly in cruise, most not classed as potentially serious. The reason they were reported is because the equipment told the pilot about it, and often ATC did so too. Also, NASA has to take the pilot's word for it that the anomaly was caused by a PED.

Jaques, ON5MJ wrote:
"I am not aware of this but it makes sense that efficiency of AC/DC + DC/AC conversion must be higher than the use of pure AC transmission."

Yes. It makes no sense to lose more in conversion than on the transmission line.

The problem with extreme high voltage power transmission is insulator flashover and corona. Alternating current and voltage have effective values which are their peak values divided by the square root of two.

This means that peak volts times peak amps divided by two is the same average power as rms volts times rms amps.

The same average power transmission requires peak values 1.414 times the rms value, effective value, or d-c value.

In d-c tramnsmission, peak and effective values are the same 100% of the tiime, so the required d-c voltage is only 0.707 times the a-c voltage peak for the same power transmission.

Jaques also wrote:
"By definition loads vary all of the time but voltage must not vary accordingly."

Use of d-c eliminates reactance as a cause of voltage variation. It also eliminates "skin effect" as an impefance so that the entire cross-section of the line is used.

The case for extremely high voltage d-c transmission is pretty good.

Best regards, Richard Harrison, KB5WZI

at
> a distance of 1/4-wavelength the voltage at the fault can rise to a
million
> volts or more.
>
> How do you compute this ?
>
---

It is computed in exactly the same way at 60 Hz as it is at 60 MHz.

A 1/4-wavelength line behaves as any other tuned circuit. The voltage at the open end rises to Q times the voltage applied at the input end.

With a short-circuit line the current at the short circuit rises to Q times the current at the input end.

The Q of a tuned circuit is the reactance of the inductance divided by the wire resistance. Q = Omega*L / R.

The Q of a transmission line is the reactance of the line's overall inductance divided by the line's overall resistance. And again, Q = Omega*L / R.

Since both L and R are directly proportional to line length, for a given line, Q is a constant and is independent of length.

Omega = 2*Pi*Freq.

There are other more complcated ways of calculating the resonant rise in open-circuit voltage from the line's transmission and propagation properties. But they all give the same answer of course. Such calculations provide a means of checking for program software bugs.

The hardest part of the exercise is calculating the inductance and resistance from the line's physical dimensions and operating frequency. Which are needed anyway to calculate all the many other output quantities from the program. Q is just a spin-off.

>I've always wondered how this is done at very high DC voltages.
>Converting AC to DC is simple, but what do you do at the other end with
>500,000 volts of DC?

If memory serves me correct, the circuit topology is the same with 500kv as it 12v. They use a chopper or DC to AC inverter, but with some really big switching devices. Thyristors have come a long way, I don't think they have one device that can withstand 500kv, they have to string 2 or 3 in series.The largest inverter I have worked on was about 4kv, but it seems they now have them that will go to 500kv. Also, don't think it is all that new, the first 500kv dc transmission line went into service in the late 70's.

Dave, try these:

Boeing has investigated alleged interference from portable electronic
devices (PEDs) and concluded:

"As a result of these and other investigations, Boeing has not been able
to find a definite correlation between PEDs and the associated reported
airplane anomalies."

You can look this up at:

http://www.boeing.com/commercial/aeromagazine/aero_10/interfere_textonly.html
Aero 10 - Interference from Electronic Devices

Here's another one:

http://www.rvs.uni-bielefeld.de/publications/Incidents/DOCS/Research/Rvs/Article/EMI.html
Electromagnetic interference with aircraft systems

Absolutely, has become a big problem with independent contractors in many building (especially hospitals). When I did a major rewire in the early 1990s (to EIA/TIA specifications), I pulled out so much cable and found so much out of compliance work .. that the engineering department of the hospital thanked me and the legal counseling firm sent me a big gift for reduced risk and potential litigation costs.

> Fred F.

YES.

I was on a flight from Toronto to Tampa a few years ago and somewhere over the Carolinas the pilot came on the PA and calmly informed us they have spent the last 45 mins trying to find the source of a buzzing noise on their radios. (He also reinforced the fact that they were all still working, but there was a buzzing noise on the audio.) He politely told everyone to turn off any electronic devices they may be using. The flight attendants quickly verified passenger compliance a few minutes later. About 10 mins after that, he came on the PA to say it was gone and instructed everyone to leave them off for the duration of the flight, not that there was any danger, but it was distracting to have a constant buzzing coming over the radio.

I did notice a couple of laptops had been fired up, but sitting in your seat is not exactly an ideal vantage point to see what everyone else was doing.

Do I think someone's radio is going to make the plane fall from the sky? Of course not. Is there a remote possibility it could cause birdies or other RF anomalies that 'could' affect things? Sure.

On one flight, a few years earlier still, WITH the ok from the flight deck (you know, in those friendlier years when you could say 'hi' through the open cockpit door when you were coming out of the bathroom) I used my FT-470 handie for a few mins. The pilot knew what ham radio was, knew I was going to be on UHF (because I told him that's where I would try for a quick QSO) and he very politely said "Sure, but only for 5 minutes, then turn it off. What seat are you in?" I thanked him kindly, returned to my window seat, and did manage to get into some repeater in Maine for about a minute or two. The funny thing was he was in the galley as we were getting off the plane, I thanked him again, and he asked if I had any luck, I said 'yep' and asked him if I came over anything up front. He smiled and said "Nope, and we were up there looking to see if you would."

The purpose of my sharing this snippet from many years ago is not to illustrate there's no danger in using a receiver (or in this case, a low power transmitter) while on a plane, but using one does not

automatically imply you're going to write off the comm/nav systems.

Your doubts do not stand up to empirical evidence. Stick to assertions that have a basis in fact and not just in your mind.

The whole point is to not weaken the chain of redundant flight safety features just to allow a piece of meat cargo to be electronically entertained.

> Now the same considerations apply to flying the approach and landing,
> but the pilot would rather not have to deal with potential

And all passengers will immediately comply, because they are all concerned about not creating a dangerous electronic environment. Games will be halted, spreadsheets closed, and porn movies terminated. Cabin attendants will notice immediate 100% compliance, and will not be distracted from other duties to repeatedly remind, cajole or threaten recalcitrant passengers.

Fred, your world is much different than any I have ever seen.

> a fire? Will the feeble RF emitted by the LO even be detectable
> OUTSIDE the plane, where the plane's antennas are located?

It's so damn complicated that nobody can answer the question. Airliners are going in the direction of all-electronic flight control and management systems. Somebody's LO won't affect fuel consumption, uhh, unless it affects the microprocessor or sensors controlling the engine. It's unlikely, a lot of work goes toward making it extremely unlikely. But remember, I said unlikely, not impossible.

Ice on the wings? What controls the de-icing boot?

Blow a tire? Is the braking circuit all-mechanical, or do you have something akin to power boost and anti-lock sensing?

Is the LO detectable outside the fuselage, near the antennas? YES, damn it, YES. I have measured it, with calibrated field strength meters. Don't give me your damn dumb opinions when I have seen the results myself. And is the LO emission strong enough to degrade or deny a navcom signal. YES or MAYBE or COULD BE. It depends on the passenger's radio, how he holds it, is he next to a window, is the fuselage unusually leaky to RF, what seat is the passenger in, what station is the radio tuned to, are the batteries new or weak, how weak is the navcom signal, what is the attitude of the aircraft, is the navcom receiver getting old, even are there multiple passenger receivers acting on the navcom (if they are all like you, how many of 300 passengers will have personal electronics running?).

The POSSIBILITY of interference is undeniable. The PROBABILITY is very difficult to predict. The safe course is to deny you your entertainment for several hours to ensure maximum safety. Is that too much to ask of you?

Not to cast aspersions on Boeing research, as they are quite reputable, but
if they had found correlatable evidence of PED's interfering with avionics,
who gets sued? The passenger, a Hong Kong radio manufacturer, or the
aircraft builder?

In any case, the reports of interference keep coming in, despite the
difficulty of replicating the problem. Obviously, the problem is rare and
elusive, but, as in most Electromagnetic Compatibility issues, the easiest,
surest, and cheapest cure is to control the source of the problem.

Just turn off ALL passenger electronics for the duration of the flight. Read
a book for 2 hours, and let your kid kick the seat in front of him.

Yes, that did not go by un noticed Mike. Over the years I have
probably ticked off every one of those who offered valued advice when
really all could have ignored my post, I did appreciate that.
On a side note, I have just ordered some powder coating which I will
place in a airiated bowl , I can then immerse a rotary capacitor in it
so I can up its voltage rating. The gap between the plates are pretty
wide so I am hoping to make the powder coat quite thick. Haven't heard
Of anybody doing this to avoid the high cost of vacuum capacitors but
that maybe because the idea is a failure.grin
But if it works out O.K. some loop antenna makers might want to try it.
Art

It also illustrates the safety concern. Although there were no observed improper responses from the aircraft avionics, "we were up there looking to see if you would" (cause a problem) is very disturbing. You added to the pilots' workload for several minutes, involving them in an interesting science project. The cockpit is normally a very busy place, so what tasks were slighted to allow time for your project?

How would you have felt if the flight crew was diverting some of their time to help somebody with a tough crossword puzzle? Was a Maine QSO worth it all? I'd have given you a whole quarter to pull the battery from your HT!

Years ago I was flying in a friends private plane. I used a Ht on 146.52 to make some contacts. My friend announces that we are lost. It took about 10 minutes before I found a landmark and got him following a road to the airport. My friend believes that the HT interfered with his radio compass and put use off course. After the HT was turned off and time was allowed, the compass returned to normal. I don't know how it happened, but it did! Now I just carry my ht on the plane and do not operate!

Jacques:

I wonder if the actual concern is not frequency/phase differences between isolated systems? If the two grids (Sweden,
EU) are not already interconnected, and the required control protocols established, then that might be the real
difficulty, and it was called SWR, since the other is much more difficult to explain to lay persons. But, take heart!
This month's Transmission & Distribution magazine describes a new device called a Variable Frequency Transformer (VFT)
which can couple up to a megawatt of power in either direction between two systems which can differ in frequency up to
several cycles per second. The first one has just gone on line at Hydro Quebec's Langlois substation between Quebec and
upstate New York.

I have a small 1 watt transmitter. I have a simple goal of using it to cover my horse so I can tune the same music throughout.

I have tried a variety of antennas to get it to work, but have been largely unsuccessful. I guess I don't know what I'm doing!

My latest and best antenna is a j-pole I built with copper pipe and mounted inside my garage. No matter where I place it in my house though I am simply unable to create a quality signal that carries more than 50 feet.

If anyone is willing to give me some tips I'd be very appreciative.

By gosh, that might just work! I don't know much about powder coating,
but since they do have powders designed for electrical insultation
properties, you might have a winner.

Just make sure to let us know!!!

And it would be a great thing for my loop. At present, I have a
trombone cap, and it wears out the mylar insulation as I use it.

Your poor horse (house - grin)

Might be worthwhile using leaky coax (radiates over its length - often used in road tunnels and mines) or maybe working out an antenna splitting exercise to various parts of the house. (ie two or more antennas) Use 1/4 wave (or odd multiple) Q sections at each antenna and combine them with a T connector before plugging into the TX. You will of course get occasional nulls where two antennas patterns meet out of phase.

A "badly fed" antenna at one end of the house with the TX at the other may radiate enough from the feedline to make the system usable. I am talking about making a deliberate mismatch here that still looks like 50 ohms at the TX. My first thought here would be to use a 4:1 coax balun at each end and use 300 ohm ribbon in the middle for maybe 30 feet. In odd places I'd then spread the 300 ohm ribbon conductors apart so they radiate a little more..

You may even find that placing the current good antenna in the roof space might work better.

Cheers Bob VK2YQA

Hi Bill,

Not sure about EZNEC Demo, but EZNEC 3.0 models it and gives Source Data (SWR) in the 600 to 1200
ohm range. Maybe you should check your connections and try again. For what it's worth, the pattern
is like most large horizontal loops, except for two large lobes in the direction of the top corners
of the tee.

Well, if one of the light bulbs goes out, they'll blame it on the nearest ham :)

Seems pretty safe, but I still wouldn't do it without permission.

I'm like that when I drive.
I'm in the left seat, it's my car and my ass, and I make the decisions.
I have actually had a passenger throw a fit because I wouldn't make a left turn that I wasn't convinced was safe, in the 1-2 seconds I had to look at it when the passenger hollered "turn left here". He got to walk home.

MFJ have a balanced line tuner out, my friend has one and says it's great. I have built several Z-Match tuners and swear my them, they are easy to make if you can get the parts. It depends what sort of power you intend to run. Linear Amp UK make a high power balanced line tuner, you can find thier website here: http://www.lauk.karoo.net/

Hello
Yes I am aware of the Matchbox, having been licensed since 1964. In
those days the Matchbox was still "new", Hi .
They have a limited matching range. They can work great on some
antennas and bands, and not at all on others.

Hi all,

As i have not the place to raise a large beam. I've been searching
different information sources for an HF antenna that doesn't need to
much space.
In the end i got stuck with the antenna's mentioned above.
Has anyone used the 3 of them ?
At this point in time, I'm leaning towards the Hustler for the
performance and the Diamond for the eassy set-up.
I'm looking forward to the feedback of people that have used these
antenna's before.
Kind Regards, Karel (ON4KVK)

"I have no trouble receiving FM radio broadcasts on a small am/fm radio
I sometimes listen to while onboard commercial jet sirliners (flying at
cruise altitude), but I bever seem to be able to pick up AM radio
stations. It`s just static across the AM band.

Any explanation for this?"

Fuselage of the airliner acts as a waveguide below cutoff frequency
(where diameter is at least 1/2-wavelength). Below cutoff, attenuation
soars rapidly.

FM wavelength is about 3 meters. AM wavelength is about 300 meters.
Propagation of FM inside the fuselage is OK. Propagation of AM inside
the fuselage vanishes quickly.

You need to stick the suction cups of your Zenith portable`s Wave Magnet
to a window to get AM reception.

Use twinleaad between the transmitter at one end of the house and a load
resistor at the other end. Twinlead will leak enough due to imbalance to
be received all along its length.

Works for 2-way radio operation in tunnels, etc.

Hello Richard,

Even with your redefined version of matching, individual generating
stations don't explicitly match to the load reactance or (certainly
not) load resistance. A little generation 101. (This goes a little
beyond the scope of discussion, but I throw it out because I think it's
interesting.):

Generators operate in two modes: Isochronous (single generator
supplying local bus) and parallel (multiple generators in parallel;
connected to a grid).
The operator has two main controls: Steam (or whatever) flow to the
turbine or other driver, and current to the field.

In the isochronous mode, varying steam flow causes the speed of the
generator to change. It also varies the amout of power delivered. In
the parallel mode, the generator can't measurably push the speed of the
grid, so increasing steam flow only increases the electrical power
output.

In the isochronous mode, varying field current changes the terminal
voltage of the generator. In parallel mode, varying field current
can't significantly change grid voltage. But it does change the
reactive power output (MVAR or kVAR) of the generator, as you said.

The normal mode of operation for a large generator is in parallel with
the grid, so the operator is using steam (diesel, water, hamsters,
etc.) to regulate real power output and field current to regulate
reactive power output.

Now some anecdotal stuff about how generators are operated. The system dispatcher requests individual generators to adjust their power and VARs to match load. This isn't impedance matching, it's simply supplying the demand. In the case of VARs, the goal is both to supply the demand and to equalize voltage across the system, not to cause any kind of mathematical match between the generator's internal X and the system's X. Oh yeah, I said earlier that individual generators don't appreciably affect grid voltage. That's true, but locally they do have an effect, like tent poles in a big canvas. So the local stations are both supplying their share of the total reactive load and propping up voltage in their area. (The operator increases VAR output by taking his excitation switch to the "raise voltage" position.)

Anyway, I digressed from my anecdotal stuff. At my plant, the generator puts out 1050 MW 24/7, but MVAR may vary between 0 (or slightly negative) and 200 MVAR. So we're not matching to any specific impedance, but supplying load and maintaining voltage.

A story transmission guys like to tell is how they may use open ended transmission lines as a kind of capacitor bank. Say there's a line 100 miles long from my plant to somewhere that's not needed to carry load. The system controller might connect it at my plant's end but leave the breakers open at the far end. A line has both capacitive and inductive reactance of course, but when unloaded, the capacitive dominates. So the trick of the trade is to use it to supply reactive MVARs. The point of the story in this context is that the controller isn't concerned about SWR on this extremely mismatched line.

Another possibly relevant story. We connect our emergency diesel generator to the grid for testing and load it to about 3000 kW and typically from 0 to 100 kVAR. But to fully test the excitation system, the kVAR is at some point raised to 1400. The point being that the generator can be operated anywhere within its rating, with no need to match to any mysterious impedances out there in the world. Makes sense when you think about it. Who would want a generator that was constrained to operate at some fixed ratio of real to reactive power?

For portable operation in the 14-30 MHz range, I use a small, handheld transmitting loop. Here is a web page describing it and how to build one from inexpensive materials. The page also links to other pages with good information on loops.

http://dt.prohosting.com/hacks/antenna/magloop.html

I chose the loop because it is actually possible to operate while walking around. Obviously if you are able to erect a larger antenna at your operating site, you would be able to get better performance. My loop is about 30% efficient at 14 MHz, theoretically delivering about one S-unit less than a half wave dipole.

Source record: 85303

For all you wireless experts out there... I'm talking about the retail off-the-shelf 2.4GHz video sender-receiver from RadioShack and places alike. How good are they? Specific questions:

- Do they interfere with household powerlines? What if there's a lot of them? What about flurencent light?
- How good are they going thru walls? Concrete walls?
- Do they bounce off physical objects? Like people walking thru the signal path?

I'm thinking of deploying them for a live cast of video cam to a TV in another room in a building. The distance is not great, probably just 50-70 feet. But the problem is the path way is a z shape corridor so that non-existence line of sight has to go thru multiple concrete walls and possible corners....

I'm thinking about using coax using RF modulation if this is not possible.

Ernest

Thanks very much for the interesting and informative tutorial from
someone in the industry. I have one question:

Nick wrote:
> . . .
> Another possibly relevant story. We connect our emergency diesel
> generator to the grid for testing and load it to about 3000 kW and
> typically from 0 to 100 kVAR. But to fully test the excitation system,
> the kVAR is at some point raised to 1400. . .

If your customers' loads were, for the sake of argument, purely
resistive as seen at your power plant output, then the voltage and
current would be in phase at that point. But in order to make your
generator produce "reactive power", the voltage and current have to be
forced out of phase at the generator. How is this resolved? Is that
reactive power "delivered" to (actually swapped back and forth between)
other generators in the system -- that is, do the other generators in
the system shift their own phase angles so that the V and I can be at
some angle other than zero at your generator output (and, necessarily,
also at the outputs at other generators in the system) yet in phase at
your customers' loads? Or do you have some local bank of reactance that
you can switch in to feed the "reactive power" back and forth to when
you run this test?

>Thanks!

I think you're going to have to make a choice between mfj products
with "okay" components and reasonable prices, versus much higher
prices for a Palstar (or Linear Amp) tuner with deluxe components like
they used in the old days. There's not much in between.

FWIW, my "wretched" mfj 989c T-type tuner easily gives a 1:1 match on
an 80 meter-w/ladderline dipole on all bands between 80 & 10 meters.
Mfj also makes a couple of balanced-line tuners, one in the $200
range, and the other in the $500 range.

THe only alternative I know, Ten Tec sells their variable caps and
variable inductors that they use in their tuner as open stock items.
You could breadboard your own tuner with one of the easily obtainable
circuits on the internet for a balanced design. (Do a Google on
Richard Measures.)

Surplus Sales of Nebraska also has a plethora of variable caps &
inductors...

This is matching explicitly. Not quantifying the load does not make it something other than R ï¿½iX Ohms

When quantified, it would undoubtedly lead to very small Rs and Xs, but all the while, the angles they resolve to are always significant.

In every sense of the term Matching, there is not a jot of difference between these applications (AC/RF) except frequency and magnitudes of voltage and current (and not always that).

>This isn't impedance matching, it's simply supplying the demand.

Absolutely no difference between applications.

>not to cause any
>kind of mathematical match between the generator's internal X and the
>system's X.

Not demonstrated, in fact your entire recitation argues to the contrary. My Power Transmission handbooks say quite explicitly that manual or automatic operation attends to the phase shift by necessity. Even if you don't calculate any quantified value it remains as a mismatch until intervention.

Trying to draw this back into the Conjugate is, again, a misread of the distinctions between Conjugate and Z Matching. The two are frequently mixed in discussion (through error), but they are not the same.

>So we're not matching to any specific
>impedance, but supplying load and maintaining voltage.

This statement is simply unquantified Matching.

>A story transmission guys like to tell is how they may use open ended

This is classic matching technique at ANY frequency and has been part
of the canon for more than 100 years.

>So
>the trick of the trade is to use it to supply reactive MVARs. The
>point of the story in this context is that the controller isn't
>concerned about SWR on this extremely mismatched line.

Actually, the concern is quite fundamental and has also been part of
the canon for more than 100 years.

>Who would want a generator that was
>constrained to operate at some fixed ratio of real to reactive power?

Hi Nick,

Who would want a generator that was constrained to supply only
toasters? Such strawmen arguements can be lined up from here to the
moon.

One of my Power distribution handbooks (ca. 1907) is not shy to the
matter of Generators seeing the products of mismatches:
"Thus a wave passing from one part of a circuit to another
having a greater ratio of inductance to capacity will develop
an increased voltage and decreased current. This
explains the breaking down of windings, due to
surges entering them."

I don't have to say SWR for it to be evident in the nature of the
description above. I don't have to say Z matching for it to be
evident in the nature of the corrective action. I don't have to say X
for it to be evident in the myriad of phase drawings and calculations
that are offered page after page.

The old practices could measure Gamma or Rho as we describe it in this
forum. Calling it VAR does not make it a mysterious process confined
to 50/60 Hz, it is simply a term that describes the same thing and
follows the same dynamics and is reduced by the same operations. We
shift the phase using a variable capacitor or a variable inductor. In
the plant the same thing is done through adjusting field excitation
(or any number of tricks that are available to the RF craft too). The
trig is identical as are the results.

Not at all; however, there IS obviously a connection between
various flight control functions (such as, say, the autopilot) and
the information given by the avionics (esp. "nav" radios using
ground-based sources such as VORs, etc.). It's not going to
"send any plane into a tail spin", but it can certainly cause some
problems.

You DO realize that these are on very different frequencies, and
that the emissions of an FM superheterodyne radio are very
likely to fall right in the aviation band, don't you? Hint: if you have
to go look up "superheterodyne" to understand this question, I
have serious doubts regarding your qualifications to comment on it.

> AM radio and the size of airplane windows - but what about the effect
> of ALL the windows on a plane? Don't they create a much larger
> effective apperature when you consider all of them?

No. It's not the TOTAL area of the "apperatures" [sic] that
is important, it's the size of the individual openings. If this were
not so, then a conductive mesh could never be effective as a
shield.

> And since the
> plane isin't grounded, isin't the exterior shell of a plane

No. "Ground potential" has absolutely nothing to do
with it. Hint: what do you think is the RF environment

within a perfectly conducting sealed enclosure, with
respect to outside sources, even if that enclosure is
completely isolated from any other surface or conductor?

> in Flight Simulator marked "Pitot Heat", what is that?

A pitot tube is a tube which protrudes from the aircraft
body into the path of the air through which the aircraft is
flying. They are used for such things as determining airspeed
(which is the speed of the aircraft through the air, not over
the ground), and in some meteorological conditions are
prone to becoming clogged with ice. Hence, "pitot heat"
is just that - the switch in question controls a heater (most
often, electric) built into the pitot tube, which keeps in clear
of ice. Losing pitot pressure due to having the damn thing
plugged up is generally considered a Bad Thing, and
unfortunate events have been known to follow such an
occurence.

The 2.4 GHz signal has a very short wavelength, and tends to bounce
around from various surfaces quite a bit. Multipath interference is a
very real issue. Moving the transmitting or antenna a few inches can
make a big difference in the signal quality.

>I'm thinking of deploying them for a live cast of video cam to a TV in
>another room in a building. The distance is not great, probably just
>50-70 feet. But the problem is the path way is a z shape corridor so
>that non-existence line of sight has to go thru multiple concrete walls
>and possible corners....

My own experience suggests that you'd be pushing things quite hard
under those circumstances, and would likely not get acceptable signal
quality.

I used one of the off-the-shelf 2.4-gig senders for a year or so, to
retransmit a video signal from a TiVo recorder to a TV in a bedroom
about 30' away. Signal quality was tolerable but not great...
definitely not as clean as a coax could provide. The signal was going
through several sheetrock walls and a cabinet door or two - this was
enough to weaken the signal quite a lot, compares to a straight
line-of-sight path.

If your signal is going to have to go through concrete walls
containing steel rebar, and is going to have to go about twice the
distance I was dealing with, I think you're going to have a terribly
weak signal at the end of the path.

The other problem is one of interference. These devices operate in
the 2.4-gig ISM band, which is becoming extremely crowded these
days... especially with 802.11b/802.11g wireless networks. No matter
which channel you select, you're likely to find that your video image
suffers from visible interference due to 802.11b and some wireless

phones...

... and the use of any microwave oven, anywhere within hundreds of
feet, will probably wipe out the picture entirely. Microwave ovens
leak a lot of RF, and it's right in this band.

>I'm thinking about using coax using RF modulation if this is not
>possible.

I think you'll get much better results that way.

> Jim

Jim, your original query and subsequent comments leave a couple of questions:

1. Is an ATU desired?
2. Will it operate a balanced line? (other antennas as well?)
3. Why is isolation from ground so important to you?

Radio Works puts out some good products, one of them is the Line Isolator for just the situation you are possibly describing:

http://www.radioworks.com/PDFLineIsolator.htm

However it should be noted that this is offered by Radio Works (in my opinion) mainly because they promote the Carolina Windom style antennas, which are designed to radiate vertical components of feedline. Most antenna types, especially anything using a Balun at the feedpoint would have no such radiation on the feedline or shield. Antennas requiring good RF ground or radials would do so, those that don't still require bonding and grounding for lightning protection, at least in any area that can have lightning. So the multiple use of line isolators, and/or your insistence on having all components isolated from ground may correct RF problems that should be addressed at their cause, and at the expense of maintaining safe bonding and grounding of the station equipment for lightning protection.

As Bob Miller also added (fwiw): I use two MFJ tuners, the 962D 1.5kw air-core inductor and the 994 600w ATU "Intellituner". Both perform very well for me on end fed wires and dipoles. Isolating anything in my station from ground is out of the question, as it should be for anyone who remains connected to either or both power and antennas during thunderstorms.

MFJ will sell the roller inductor they use in their tuners. I bought one at the MFJ exhibit at a hamfest. They indicated that they will sell pretty much any part of their products if you call and let them know what you want. I built my tuner out of the MFJ inductor and Ten Tec capacitors. It's my MFJ Tec tuner. Parts cost around $150, works well and has handled the legal limit.

Richard Clark wrote:
"The trig is identical as are the results."

Yes, but the equipment often takes different forms. The best place to get rid of circulating current in the transmission line is at the load, before it causes additional line loss.

For signal lines a capicitance or an inductance often is formed by a line stub.

For power lines a capacitance is often produced by an over-excited synchronous motor or motors. Some constant speed loads are suitable for sychronous machines. Such a machine drawing a leading current has been called a rotary capacitor. Its current draw and capacitance are controlled by its excitation.
Most induction motors and industrial loads have lagging currents. Power factor correction requires the production of an offsetting leadng current.

Best regards, Richard Harrison, KB5WZI

Hello Jack
Yes, the tuner is required, because I use a balanced line to feed a multiband doublet.
The issue is placeing a 1:1 balun at the input of the tuner, rather than the output. In order to do that with an existing T match type tuner, all components must be isolated from ground. This is uncommon, because a typical T match grounds one side of the inductor.
I have read that a 1:1 balun at the input of a T match is desireable over a 4:1 at the output.
Thanks

Hi Richard,

One of my old references offers support to this in the terms you expressed following this quote above:
"Power factor correction may be made on transmission lines, whereby the voltage regulation may be materially improved, the generating capacity increased and the copper losses reduced. This correction may be made by the over and under excitation of synchronous apparatus at the receiving end of the line. When used for this purpose exclusively, such apparatus is called a synchronous condenser. ...its sole function being to regulate the power-factor...."

The difference between this matching to the load, and say Gamma matching to an antenna is in name only - same problem for both disciplines, same approach to a solution. It stands to reason that when this technique is performed at the source end, that it is still the same "synchronous condenser" metaphor; hence we have electro-mechanical artifices to construct a phase offset to a reactive load.

If everyone could afford gold-plated rigs, then they might consider paying for the same artifice of the "synchronous condenser" metaphor in place of their tuners. In this regard they would be using Gyrators (artificial reactors). Through the use of feedback in an operational amplifier dedicated solely to this purpose, you can invert the use of a capacitor to appear to be an inductor (or t'other way 'round). Here, this particular circuit probably outnumbers all examples of tuners AND power line correction (it is exceedingly commonplace in switchers).

David
I reviewed your page to find out how the capacitor was made
and how it was driven. Unfortunately I could not figure it out!
One thing I thought about as I read the page was the soldered
joints and its added resistance. It would be interesting if some time
you could use some aluminum foil preferably with adhesive backing
to go from one end of the loop to the other in a continuous strip to
gauge
what difference the jointing made on the resonant frequency.
Adhesive tape can be found at any hardware store in the heating and
cooling
ducting section.
Regards
Art

I can think of a couple of things. Firtst, you may have insulation with a metal backing between the house and garage; not good. Also, what is the polarization of the receiving antennas? If they are horizontal, you would be better off with a horizontal transmitting antenna. You might try a dipole in the attic, under the insulation. That is, on the ceiling of the room below. If the insulation has a metal backing, take it off from directly above the antenna. This should be in the center of the house. Basement might work just as well. BTW. I don't think your gizmo puts out 1W. That would easily go a mile. Probably 1 - 10 mW. Lastly, make sure the transmitter is on frequency. Going 200 KHz up or down in either direction should be equally bad.

Hello Roy,

Good question and one I had considered addressing in my already over long post. In general "the grid" is viewed as an idealized source or sink of both real and reactive power. So we can theoretically supply it as much power as we wish, and supply or take in as much reactive power as we wish. No reactive load banks needed.

So when I said generation (of both watts and VARs) is matched to demand, that's not necessarily *exactly* the case when it comes to VARs, as you guessed. Generators can both supply and absorb them to meet the need, and the net VAR output doesn't necessarily have to equal whatever the customers are offering as the load at any given time. BTW, in the power biz, we have the convention of "supplying", "outgoing", or positive VARs to describe reactive power out from the generator to a lagging (inductive) load and incoming, or negative VARs to leading (capacitive) loads. Incidentally, real power must flow *out* only. We have reverse power (anti-motoring) relays to trip the unit off line if this rule is broken.

The tendency of generators to exchange VARs when in parallel leads to a stability problem in excitation control. A slight mismatch in excitation systems can lead to a huge exchange of VARs and resulting overcurrent. So excitations system incorporate what is known as a "droop" feature which essentially provides a negative feedback based on reactive current. Increased VARs out tends to reduce excitation, stabilizing the system. Droop is typically switched "off" in isochronous (one generator isolated) mode. There's an analogous "droop" feature on the governor for speed control when in parallel.

Not sure if your question included this, but it's interesting to consider just how a generator produces out of phase current when connected to what we're essentially considering to be equivalent to an ideal voltage source, since by definition the generator's terminal voltage must equal that of the source (grid). As I see it, the key is that the generated voltage, Eg, is n ot the same as the generator's terminal voltage, Et. There's a drop across the armature reactance, so Et equals Eq minus that drop. Interesting that out of phase currents produce drops in phase with Eg ... Well, I thought so anyway. Current is Et minus Eg divided by Za (armature impedance). Changing excitation changes the magnitude of Eg (Et is fixed by the grid and so is an anchor point). By fooling with the phasors, I think you can see how changing excitation changes the phase angle and therefore controls VARs.

How *power* is controlled is beyond the scope of this discussion (and maybe of my understanding). But it actually is related to the angle of the rotor's physical position relative to the rotating field of the armature. That angle is dependent upon the torque supplied by the driver.

Hi Jim,

I can't imagine what's possibly gained by 1:1 in front of the tuner v. 4:1 (when applicable, some antennas recommend this, including for twin-lead) after it. Can you recall the writing you saw the recommendation to isolate from ground before the tuner? I just don't see what it will do for you, but as I said there is at least one good reason not to do so. Ungrounded and especially unbonded equipment should be disconnected from antennas and power supplies before the chance of a thunderstorm. An exception could be if you totally isolate the antennas from ground, and no balun can safely do that. But a similar principle called a high voltage isolation transformer could, and so could a fiber optic isolation transformer. Both are pretty expensive alternatives to staying with generally accepted lightning protection plans for the shack. Even if you intend to toss the feed out the window before a storm, I'm still curious what is gained by a 1:1 between transceiver and transmatch.

73,
Jack

Here is a quote from one site:
Of interest is the 1:1 balun mounted at the input of the tuner (rather than the output where it would be exposed to highly reactive loads). The various components are floated above chassis ground. When properly adjusted, the balun sees a 50 ohm load both at the input from the transmitter and at the output. Its not a perfect replacement for the link coupled circuits of yesteryear, but in my experience so far, it perfoms significantly better than competing tuners employing 4:1 baluns. I've tried a few of these matching networks and not one of them provided an output to tuned feeders even close to being balanced. The AT4K-BAL is a leg up on this account.

There are dozens of other sites, but it is all the same info..including several ARRL articles.
The issue is not lightning protection, as you suggested.
Thanks

Yes there is. The operator of the generator has the freedom to adjust
power output from 0 to 100% of rated and VAR output between the maximum
incoming and outgoing rated values. No matching required. I sense
that you are beginning to argue my side of the case for me. Please
give me appropriate credit.

No it is not. You are making oblique reference to the use of stubs in
RF matching. In that application, the length of the stub in degrees is
critical. In the one I describe, the length of the line is random; it
is being used for its capacitance only. It could be replaced by an
equivalent capacitor to produce the same effect. The same is not true
of a matching stub.

Your first post did make it, and I also found that reference that shed no
light, but further:

http://fermi.la.asu.edu/w9cf/articles/balun/ (quoted below)

4 Baluns on the input and output of unbalanced tuners:
Roy, W7EL, worked out the math for moving a current balun from output to
input of an unbalanced tuner using his model of a choke balun and found that
essentially nothing changed.

...the most sensible place to put a balun is on an unbalanced tuner's
output, like it is on nearly all commercial tuners, and not on its input

--

Interesting theory presented there, but does not support the wives tale
either.

And yes you can stand-by-for-fireworks if you think lightning protection
isn't an issue. Anyone that thinks "floating equipment chassis" (isolated
from ground) is a good plan, lives in a place where lighting is something
they watch only on the Discovery Channel.

73,
Jack

The few balanced tuners that are being manufactured nowadays all seem
to employ the balun on the input side. To use the words from MFJ's ad
copy for their balanced tuners:

"A 1:1 current balun is placed on the low impedance 50 input side to
convert the balanced T-Network to unbalanced operation. The balun is
made of 50 ferrite beads on RG-303 Teflonï¿½ coax to give exceptional
and efficient isolation. It stays cool even at maximum power."

Basically, the balun hooks the balanced tuner to the unbalanced output
of the transceiver.

In years past, there have been heated discussions in this group as to
whether the balun belongs on the input or output -- you could do a
Google search if you're interested.

Jack
Let me assure you, my station is well grounded, Hi! I even have an abnormal passion regarding grounds.
My remark was in regarding to a "floating" balanced antenna tuner, which is not grounded anymore than is a balanced line fed doublet. Certainly everything before the tuner is well grounded. I even have a spark gap type lightning protector on the balanced feeds.
As far as the debate regarding baluns at the input or output, I would be delighted to be convinced that it either does not matter, or is better at the output..because it makes my life a lot simpler. Right now I am using about 5 feet or so of LMR400 from my unbalanced tuner to a Radio Works remote balun, terminated with 300 ohm transmitting twinlead, feeding a 40 meter doublet. Works like gangbusters.

>>>>> "art" == art <aunwin@insightbb.com> writes:

art> David I reviewed your page to find out how the capacitor was
art> made and how it was driven. Unfortunately I could not figure
art> it out!

The capacitor is made in a coaxial fashion with 3/4" polyethylene "PEX" tubing as the dielectric, and copper pipe as the plates. The inner copper tube (1/2" copper repair coupling) is the stator, and the outer tube (3/4" copper repair coupling) the rotor. The rotor slides over the joint between the dielectric and the stator (3/4" copper pipe) which have the same outer diameter.

The capacitance is adjusted manually, by sliding the rotor from side to side. I am relying on the tight fit and the large amount of overlapping copper area between the rotor and its contact to keep losses low. Also, because the sliding contact is at the high voltage end of the loop, I presume resistive losses aren't as bad as they would be at the bottom where voltage is low and current is high.

art> One thing I thought about as I read the page was the
art> soldered joints and its added resistance. [...]

Gee, how resistive is the solder? I know it's not as good a conductor as copper, but the joints fit pretty well. I'm guessing the amount of solder width in the electrical path is probably on the order of one millimeter for the entire antenna. Given that the copper loop's DC resistance is (in theory) around 40 milliohms, it's hard for me to imagine that a solder "fuse" (if you will), connected in series, would add much. But I'm prepared to learn something new -- it happens all the time!

When I was first experimenting with the design, I had been worried about the union joints, but they have something like 1cm^2 of surface contact and the copper squishes together as the joints are tightened.

In any case, your suggestion about applying a continuous conductor and checking for its influence is well taken. At least, I don't have a horrible problem or the bandwidth would be too large and/or something would be getting hot.

A device usually described as a 1-to-1 choke balun is amongst the most simple of all radio components.

Actually, 1-to-1 has nothing to do with impedance-matching or transformation, or anything else.

The choke simply allows a balanced circuit, of no particular impedance, to be connected to an unbalanced circuit, of another no particular impedance, without any significant interaction between them.

It is just a very short length of balanced-twin transmission line, like speaker cable, of no particular impedance, wound on a ferrite ring to behave as a bifilar-wound RF choke.

Loss is negligible. There's only copper loss. The ferrite plays no part in transmission along the short line, only in the longitudinal choking action.

If there are any ferrite losses they only occur due to the very small longitudinal current - which is what the choke is doing its best to get rid of anyway.

When used at the end of an antenna feedline a choke balun is just a short continuation of that line, albeit of a different impedance. Which is of no consequence.

At the junction of the balanced-to-unbalanced lines, such as coax to open-wire, there's going to be a large mismatch anyhow. But that's what the tuner is for.

The balun does indeed have an impedance transforming property as does any other short length of line. But in the case of multiband antenna systems it merely transforms one set of random-value impedances to another random set. Which, in effect, leaves things as they were.

The average impedance of speaker type cable is about 140 ohms which, for perfectionists, fits very nicely between 50-ohm coax and 450-ohm ladder line. But it hardly matters.

The length of line wound on a balun should not exceed 1/8 wavelength at the highest frequency of interest, at the lines own velocity. Choke action at the lowest frequency of interest depends on number of turns and permeabilty of the ferrite.

For multi-band operation a choke balun should be used. It is far better than fixed-ratio 4:1 and 9:1 baluns which involve wishful thinking and are best used over relatively narrow bands.

Choke baluns also make balanced tuners redundent. Who wants to crank two roller-coasters when one will do.

Jack, I do think there's some confusion here. In cases where the balun is a part of the tuner input, the tuner chassis is usually connected directly to the transmitter chassis through the normal coax. You can ground the tuner chassis to an external earth ground if you so wish. Internally, the balanced output of the balun is connected to the "T" components at the input side. The coil, of course is not at chassis rf ground potential, but that is not relevant. It is, however, at DC ground potential (via the balun winding). I don't see any additional lightning issues associated with placing the balun at the tuner input.

>I can't imagine what's possibly gained by 1:1 in front of the tuner v. 4:1
>(when applicable, some antennas recommend this, including for twin-lead)
>after it.

The reason I've seen stated, is that many 4:1 balun designs only work "as advertised" if they're working into something fairly close to their design impedances. For example, a 4:1 balun intended to match 200 ohms to 50 ohms, will only provide a 4:1 ratio and good current balance and efficiency when matching impedances fairly close to those.

If you put such a balun at the output of a wide-range transmatch, and try to match up a difficult load, then the balun might "see" something like 750-j250 or 25+10j on its "200-ohm" side. The result might be poor current balance on the "balanced" side, or excessively high current flows which would require de-rating the balun's power handling capability. "Voltage" baluns seem to be most vulnerable to this sort of problem.

Putting a 1:1 balun on the input side of the tuner, and using a fully-balanced or pseudo-balanced tuner is one way around this, since the balun "sees" only the impedance load for which it was designed.

Another approach, often suggested, is to use a 1:1 transmission-line current balun on the output.

Using a link-coupled tuner (a classic Matchbox, or a Z-match) is yet another option.

Bob Miller wrote:
> The few balanced tuners that are being manufactured nowadays all seem
> to employ the balun on the input side.

It's difficult to put a "Balun" on the output of a balanced tuner.
The tuner is balanced and the feedline is balanced. Any device
designed to reduce common-mode currents at that point should
properly be called a "Balbal" - and they are relatively difficult
to build for the desired balanced Z0.

> In years past, there have been heated discussions in this group as to
> whether the balun belongs on the input or output -- you could do a
> Google search if you're interested.

Things got carried away during those heated discussions. What I
got out of it is that a balun on the input is just as effective
as a balun on the output. What most people apparently got out of
it is that a balun on the input is absolutely useless. So another
old wives' tale is born. If the following statements are not true,
someone please correct me.

If the common-mode currents don't change as a result of moving the
balun from the output of an unbalanced tuner to the input, essentially
nothing changes. The balun continues to be just as effective against
common-mode currents and the stress on the balun remains the same.

If the common-mode currents increase as a result of moving the balun
from the output to the input, the effect of the movement is negative.

If the common-mode currents decrease as a result of moving the balun
from the output to the input, the effect of the movement is positive.

Bottom line is that one needs to measure the common-mode current to
determine if *any* change is effective. A ferrite toroid with a few
turns around it driving a 1N34 circuit is an inexpensive and effective
way of measuring common-mode current. In one experiment that I ran,
moving the choke from the output of the balanced tuner to the input
actually reduced the measured common-mode current for that particular
configuration. But without actual measurements, results are unpredictable.

Essentially the same function can be obtained by wrapping a few
turns of coax around that same toroid. The impedance looking
into my balanced feedline is between 35 ohms and 85 ohms so
teflon RG-400 works very well.

> The average impedance of speaker type cable is about 140 ohms which, for

It matters even less than that, Reg. :-) On a 450 ohm feedline with SWR
not equal to 1:1, the impedance looking into the feedline will *never*
equal 450 ohms.

What's wrong with putting a 1:1 choke on both input and output
to double the impedance seen by the common mode current?

David

I have had good success with a vertical wire of whip that is longer that a 1/4 wave on the lowest frequency with a variable capacitor at the base for tuning. I use a sectional military vehicle whip that is about 20' long mounted on a wooden broom handle that is pushed into the ground. The capacitor is connected between the centre of the coaxial feed and the bottom of the whip. Then it is just a case of connecting a couple of radials for the band that you want to work and tuning the cap for minimum VSWR. I have worked all over the world on the higher bands using my FT-817 with 5W. it takes only a couple of minutes to set up and is very efficient. The whole antenna weighs about a pound and will fit inside a rucksack. I have used it with 100W even with a receiving capacitor, as the cap is at a low voltage point there is no worry of flashover.

If you want more information please email me and I will send you a picture.

Hi Chuck (and Jim), I was unclear on what the benefits would be, hence my questions to Jim (and the Group). But the file I referenced earlier also questioned the benefits, and explained the need for floating the tuner when a Balun i used in front of it, which would be a very bad move if lightning protection was an issue. There would be no ground connection to the tuner, leaving it as a sacrifice gear but inside the shack!. That's not all that uncommon to sacrifice a tuner by the way, but usually seen where the tuner is up in the air at the feedpoint. Marine applications often use this configuration. I don't! Hi!
--
6. Conclusions
As noted by Roy Lewallen, W7EL,[2] putting a choke balun on the input of an unbalanced tuner to drive a balanced line is useless. It introduces a ``hot'' tuner case which must be isolated with no benefit over putting the balun on the output.
--
I agree that a 4:1 after the tuner (or after coax from tuner to feedpoint where laddr-line begins) is a compromise at best, offering beneficial performance at some frequencies and degradation at others. All a matter of choices I guess, make the decision that's safe (first) and best for your needs after that.

As always, I find this group shakes out great comments and explanations. If Roy L wants to add something to this I'm sure we would all be interested.

There have been numerous postings in various scanner, shortwave and ham groups by people who have been ordered to turn off their radio and other PEDs.
More than one person has been ordered off, or met by the authorities on landing and at least one passenger who refused to turn off a cellphone ended up with some jail time after landing in the U.K. - it was pretty widely reported a year or so ago.

The I presume you specified AM because the LO operates outside aviation frequencies (now that LORAN A is gone), unlike the LO in an FM broadcast receiver which covers the VHF localizer and VOR frequencies very nicely.

I can't provide technical details of the operation because I don't know
them; but I am familiar with a number of totally RF screened environments
where use of electronic devices are tightly controlled. However, internal
relays are used to permit operation of cell phones - which I always
understood were specific models which had been certified for such use.

The choke on the input is *still* in series with the common-mode
current and is still performing the choking function. Moving the
balun to the input doesn't relieve the stress on the choke but it
also does NOT render the choke non-functional as the word "useless"
implies.

>I did get it to model SWR with high reactances(to me anyways).
>Does this seem right? I dunno. Thanks

Hi Bill,

At this point, you need to provide more specifics. One, what frequencies? Two, did they match your experience with a physical model?

To answer your question lacking this information, yes this seems right - at least somewhere in the panorama of all possible outcomes. It stands to reason that ANY antenna, when looked at across a wide enough spectrum, will reveal both resonances and high reactances, and many combinations in between. This is just par for the course.

Now, if you find you are experiencing these high reactances in nature as well as in modeling; then try one thing: Break the wire at a point that is on the opposite side of the loop from the feedpoint and see what happens.

Roy, W7EL wrote:
"In what way is the effectiveness of a circular loop decreased by changing its shape?"

There is an old story about the kid who tells his dad about learning in school that pi r sguare. Dad replied that what school taught him was dumb. All the world knew pie are round. Cornbread are square.

Maybe it was Pythagoras who found the approximate value of pi by constructing ever more equilateral sided figures inside and outside of a circle until there was no significant difference in the lengths making up the sides of the interior and exterior figures. He could measure straight lengths. He found the value to be 3.1416 for the approximate value of pi which multiplied by the radius would equal the perimeter of the circle. Also, pi times the radius squared gave the enclosed area.

The figure which encloses the most area for a given perimeter is a perfect circle. Distorting a circle reduces the area it encloses.

Radiation from any loop depends on its enclosed area. This is intuitive from transmission line behavior. It`s often observed that the wider the spacing between the wires, the more the line radiates. As we increase the area of a loop, the distance between the wires increases. Like the transmission line, iits radiation increases.

An antenna of any configuration radiates. Efficiency is determined by the ratio of radiation resistance to loss resistance. The antenna with minimum perimeter for a particular radiation resistance will also have minimum loss with other parameters being equal.

Best regards, Richard Harrison, KB5WZI

Ok, let's start with a triangular loop with negligible loss. We feed 100 watts to it. Since it has negligible loss, 100 watts must be radiated.

You've said that the radiation must increase as we round out the triangle. So how much more radiation can we expect from a round loop fed with 100 watts? 120 watts? 150?

Sorry, my previous message was placed in the wrong thread.

I can add that 4:1 and 9:1 fixed-ratio baluns should be used only between known, well-defined, relatively narrow impedance ranges.

They are best NOT used on the transmission line side of tuners. Otherwise the tuner is forced into dealing with reactances in the balun itself. This restricts the range of antenna impedances which can be handled by the tuner.

Fixed-ratio baluns, with their excellent frequency response, are ideal on the transmitter side of tuners, i.e., between precisely known impedances. However they are seldom needed in that unusual position if the required impedance transformation takes place in the tuner itself. As it always is with a standard type of tuner and a 50-ohm transmitter.

# 3670. Vertical antenna recomendations

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-15 15:31:14 UTC
From: John <res0b06f@verizon.net>
Message-ID: <6NYvd.7201$E_6.5061@trnddc04>
Source record: 85253

Greetings all....
I'm slowly getting back into Am. Radio, currently on 2m & 70cm. (I had a General before my current call) and my knowledge of current antennas and transmission line options is really outdated.

I have a place in the remote areas of North Central Florida that's on a bluff about 125 feet above the surrounding forest. About 150' from the house is an old Satellite antenna mounting pole (really solid and substantial) that's maybe 18 or 20' tall. The big dish isn't there anymore, just the pole. I'm thinking that I would like to mount a vertical antenna on the top of the pole. I would anticipate running maybe an Icom 706MkIIG on HF and the 2m and 70cm. Many many questions come up and I could benefit from people with more current knowledge of what's available.

1. What verticals are recommended these days? (I used to like the Butternut) The 706 claims 100 watts on HF and 6M, 50W on 2m and 20w on 440.

2. With the vertical up about 18', what about radials? can I bury them at the base so I don't have guy wires draping down from the top of the pole at the base of the Vertical?

3. What suggestions for coax transmission line to make that long a run? I was thinking I would put it in Schedule 40 PVC pipe sealed as if it were carrying water, and bury it.

Although I'm out in the middle of the boonies, esthetics is still an issue, so I don't want wires showing.

Thanks for your comments...
John

Source record: 85254

Personally I've never been impressed with Butternut's quality. But maybe
that's just me.
I would look at things like the CushCraft R7 (or similar model from
HyGain). Or if I really had money to burn, the big tower from HyGain.
If I were to "roll my own", a Disc-Cone made for 40M would be great
(with continuous coverage to 6 meters, all with no radials). The down
side, large : about 40 ft tall and 35 ft across, unless you wanted to walk
under the cone, then it would be 50 ft tall and 40 feet across.

Your best bet is a copy of the ARRL Antenna Book. About $30. Pretty
informative.

Otherwise, the Butternut verticals have a pretty good reputation
nowadays. Go the the Bencher web site (they sell Butternut), and look
at some of the tech papers they have for vertical antennas. That would
be a quick way to catch up on things...

Roy, W7EL wrote:
'Ok, let`s start with a triangular loop with negligible loss."

"Negligible loss" eliminates the differences between loops of most shapes with the same enclosed areas. Area of a triangle is 1/2 its base times its altitude, if I remember.

I`d rather use 16 ft of wire to make a square loop with 4-ft sides. Side squared makes an area of 16 sq ft.

A circle of 16 ft perimeter has a diameter of 6.09 ft. Radius is 3.049 ft. Squared, it`s 9,27. and times pi it`s 20.13 sq ft.

Clearly the circle has the greater area for the same wire. Loss is based on the resistance of the wire which is the same in both cases.

For more enclosed area, you get more radiation for the same wire and loss.

As a short cut, I`ll quote Terman on page 907 of his 1955 edition:
"The radiation resistance of a loop antenna is less the smaller the loop area."

Best regards, Richard Harrison, KB5WZI

# 3679. H.F Dish Antenna update

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-15 16:54:39 UTC
From: art <aunwin@insightbb.com>
Message-ID: <1103129679.185216.177960@z14g2000cwz.googlegroups.com>
Source record: 85186

In the past I mentioned that I was modelling an antenna for 20 metres.
This antenna became a single driven element with five reflectors which
emulate a dish in it's crudish form not only in position of reflectors
but also the elements were not shaped at this time.
The following table follows what one would get for a reflective dish
used on frequencies in the giga hertz range where the bandwidth is
broader than
that obtained with the yagi format PLUS relevant atributes stay more
constant over a frequency range than that obtained with a super gain
type array.
The band width is wider than a typical yagi in that the major portion
of the radiation is to the front this.This band with is expected to
narrow and to increase gain when individual elements are shaped to a
parabolic form and
it is hoped that forward side lobes will not occur as is normal for a
long boom multi element yagi form as used on 440 Mhz.
The driven element is at a height of 76 feet over perfect ground.

Normally one would say that if results seem out of the ordinary one
should question it, so comments are requested regarding my explanations
which
lead me to think that they really are what one should expect.

Freq 14.0 14.1 14.2 14.3 14.35

Gain dbi 13.86 14.05 13.99 13.9 13.87

F/B 30 25.6 27.47 33.17 32.5

Zr 45.9 44.5 43.8 43.2 42.8

Zi -12.87 -6.52 0.6 7.84 11.54

SWR 1.32 1.2 1.14 1.25 1.34

I do not advocate the replacement of the normal yagi with the above
because of building difficulties tho it is my intention to build it.

Regards
Art

(Modelled using AO PRO with 80 segment/half wave and set up by a
consumate error generator Grin )

>1. What verticals are recommended these days?

Hi John,

Just put up as much vertical tubing as will support itself, insulated
from the pole.

>2. With the vertical up about 18', what about radials?

Use the pole as the one and only radial. You would then have a
vertical offset dipole with one end grounded. I've never seen a name
put to this, but as an ad-hoc antenna, as good as any. If you want
more radials, simply tie them in at the bottom of the pole, buried
into the ground about an inch or two (or even tacked down along the
ground every 6" to a foot or two depending upon vegetation/grass
coverage - more grass, less tacking). Don't worry about more than 10
or 20 of 1/8 wavelength of the lowest frequency.

>3. What suggestions for coax transmission line to make that long a run?
>I was thinking I would put it in Schedule 40 PVC pipe sealed as if it
>were carrying water, and bury it.

Seal it only at the highest point so that it can drain when water gets
in (it will). Always choose a pipe several times larger than your
first guess and use sweeps at the bends instead of elbows.

An alternative is to electrically tie the tubing to the pole, and
Gamma feed the pole. Same advice about ground goes. One problem is
that this one size fits all (roughly 40M and up if the whole thing
stands some 30-40 feet tall) is that the higher bands will radiate
higher and higher into the sky. You might, then, want to use the pole
to support yard-arms that hold different radiators out and a way from
the pole and each other (one reason why you had that bigger pipe
installed for each of their feeds).

>Huh? A folded dipole is a LOOP.

Hi Steve,

Richard is right, but to answer your Huh? then it could be argued
that a standard dipole is an open loop or an unfolded dipole.

Classic radiation resistance formulas that are the basis of antenna
theory introduction are composed at small sizes such that the dipole
or the loop are no where near standard sizes. Their accuracy extends
between roughly a tenth wavelength to a quarter wavelength or more in
the greatest (not perimeter) physical dimension. This is often the
same range of size employed by the Ham in the HF regions.

>It radiates the same amount of RF as a circular loop. No more, no less.

Typically, yes, but to ignore the lesson of Rr may lead some to ignore
the importance of Ohmic loss in small radiators. That is to say,
offering the sobriquet that wire has negligible loss must have some
objective correlative: in comparison to what is it negligible?

One Ohm compared to 100 Ohms is trivial, whereas one Ohm in comparison
to 10 mOhms is warmed over death. Same wire, same loop (or dipole),
but far different results for different frequencies that yield
different radiation resistances.

>Just in a different direction and more in
>the favored direction. Pythagoras who?

Yahoo Pythagoras, an Australian red-headed actor wasn't it?

F/B looks too high, you should have some big splinters off the backside.
(with a dish it can be hard to get 30)
Gain looks to be high for a 1 driven and 5 reflectors.
Does model take into account mutual effects of the reflectors?

CORRECTION
The BEAM width is wider than a typical yagi in that the major
portion
of the radiation is to the front .This BEAM width is expected to

I wrote:
"A circle of 16 ft peroimeter has a diameter of 6.09 ft."

My eyesight needs correction. It should have been 5.09 ft.

The area of a 16-ft circumference circle is 30.37 sq ft, not 20.13 sq ft.

30.37 sq ft is more than 16 sq ft, so the circle radiates more than the square for the same length of wire.

Guys, there's this thing you may have heard of called 'democracy'. It's
a flawed system of government which assumes the majority is right.

This is the government you run under. This is the government that
elected George Bush. This is the government that elected Kennedy, this
is the government that elected Nixon, Clinton, and Roosevelt. Like it or
not, there is nothing you can do about it. The system works. You have
the President that most of you wanted.

This is why websites like 'sorryeverbody' really piss me off, what are
they apologising for? Are they apologising that the system works? That
the President who had the majority of the vote was elected?

The election is over. If you want your view to be heard, quit your
whining, quit your apologising, quit your tiny blogs that few read.
Write a letter, go on a march, and in four years time, vote.

*gets off his soapbox*

To the fullest extent of the concept. See the 3rd edition of Kraus`
"Antennas", Section 2-11, The Radio Communications Link, beginning on
page 336.

Radio antennas scale to wavelength. Microwave antennas may be
impracticably large when scaled to longer wavelengths, but if built work
exactly like their higher frequency models.

Richard Harrison wrote:
> Roy, W7EL wrote:
> 'Ok, let`s start with a triangular loop with negligible loss."
>
> "Negligible loss" eliminates the differences between loops of most
> shapes with the same enclosed areas. . .

That's almost correct, but not quite. Except for loss, a triangular loop, square loop, folded dipole, or round loop radiate equal amounts *regardless of their enclosed areas* -- the amount of power that's applied to them. The round loop doesn't radiate any more than any of the others. None is one more "effective" than another, except that the patterns will be different, so one might be more effective than another at communicating in a particular direction -- but the round loop won't necessarily always be the winner.

The statements you made earlier about a round loop radiating more, and the continuing hangup about enclosed area, are based on the assumption that the loop is small and is driven by a constant current source. For a given amount of wire, the round loop has the highest radiation resistance, and therefore if fed with a constant current, it consumes and therefore radiates the most power of any loop made with the same length of wire. This is a set of conditions often used by textbook authors to illustrate some basic principles, but it isn't representative of amateur (or commercial, for that matter) antenna use. It's necessary to read and understand the qualifications given by the authors before quoting their conclusions.

For a given length of wire, you'll get the most efficiency from a round loop for a given length of wire. But unless the loop is electrically very small, the efficiency will be high enough that this won't make any noticeable difference. Making a large loop round -- or increasing its enclosed area -- won't make it "radiate better" or be "more effective".

Roy Lewallen, W7EL

# 3695. Re: Loop Antenna as Triangle?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-15 20:25:20 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10s17diimio3k63@corp.supernews.com>
Source record: 85183

It applies just as well. However, while the aperture of a parabolic reflector is about the area of the reflector, this isn't at all true of simple wire antennas like a dipole. For example, a half wave dipole's aperture is just slightly larger than a dipole of infinitesimally short length, and about equal to that of a loop. The aperture of a loop stays almost constant as the loop size is increased, until it gets big enough for the pattern to appreciably change.

Aperture is the same as directional gain (not numerically, but when one is greater so is the other), which is the same as gain when loss is neglected. Since aperture has no direct or obvious connection to physical size or dimension of most wire antennas, gain is usually used at HF as a descriptive measure rather than aperture. Note that the gain of all but an isotropic antenna is different in different directions, and therefore so is the aperture.

People with a weak understanding of the principles involved often fall into the trap of thinking that a larger antenna must have a larger "aperture" or, as amateurs like to call it, "capture area". That mistaken notion leads to all sorts of false conclusions. But the general misunderstanding of the terms are a real boon to antenna charlatans.

Roy Lewallen, W7EL

Also, the aperture is different in different directions.

With the same power input? If I apply 100 watts to the square and get (very nearly) 100 watts radiated, how much do I get from the circle? Let's see, 30.37/16 * 100 = 190 watts. If I could capture that in a screen room with another antenna, I could feed 100 watts back to the transmit antenna and have 90 watts left over to run the refrigerator to cool my beer. . .

A plain dipole 76 feet above perfect ground has a gain of about 8.6 dBi - surely you've modeled one with AO. So the gain of your antenna over a dipole is about 5.3 - 5.5 dB. (This would be a more meaningful way to state gain.) This is just slightly more than the gain from a three element Yagi, and less than a typical four element beam. The F/B ratio and bandwidth might be better than that of a typical three or four element Yagi (or they might not be -- a Yagi can be adjusted for a wide range of characteristics), but the gain is certainly not exceptional.

Sorry, we don't run under a democracy. If we did, Al Gore would have
been president. The USA is a *Republic*, not a democracy. Our Constitution
protects us from the tyranny of the majority. We don't have to drink
hemlock simply because the majority wants us to. (Socrates drank Hemlock
and died because the majority voted for it.)

>
> Why? Do you have splinters in a parabolic dish?

You have individual elements, a parabolic has continous surface. Antennas
always have splinters, with just 5 elements and no blocking you probably
have major lobes on the back side, between elements.
There will be places on the back side of your antenna that add in phase with
two or more elements, which is a lobe or splinter.
Parabolics have a rolloff on the edge to decay the field to minimize the
back lobe.

> > (with a dish it can be hard to get 30)
> > Gain looks to be high for a 1 driven and 5 reflectors.
> If you picture a balloon squashed at one end more than
> normal would not the gain increase?

What is the capture area? Each element captures RF energy and reflects it
back to the driven element in phase with the others.

Your idea has been tried very sucessfully at 450 to microwave, and they now
use flat antennas with each element phase adjusted for delay (same as
curverature of a parabolic dish) One antenna has over a thousand elements.

Hi Dave,

Wrong context. Not many can hoist a dipole that high, and finding
perfect ground is even more difficult to find - but once they do, that
2+ dB is undoubtedly measured in dBd (which is to say, compared to a
dipole in free space) which at least one of your links uses also.

Dave, Your 2+ dBi gain is for a dipole in free space Vs an isotropic in free space. Roy chose to compare the dipole over perfect ground to the isotropic in free space. The ~3dB of reflections from the perfect ground cause the additional gain due to constructive interference.

W4RLN ???? said he prefered dbi if I remember correctly. Can't remember the
reason why

> This is just slightly more than the gain from a three element Yagi, and
> less than a typical four element beam.

Difficult to compare Roy as the top reflector position moved beyond the
feed point albiet also much higher.

> The F/B ratio and bandwidth might be better than that of a typical three
> or four element Yagi (or they might not be -- a Yagi can be adjusted for a
> wide range of characteristics),

Well I thought the F/B was exceptional, especially because it stayed
relatively constant
over the band width as did the gain. I especially liked the fact that the
impedance
was in the 50 ohms vicinity where optimum characteristics of an yagi antenna
usually drives
the impedance to a low level. Force 12 emphasises that to get optimum gain
one must accept
unrealistic impedance values among other things
Can you point to a 4 element yagi where its characteristics are better in
every way?
( there must be something where this excels. grin)

>but the gain is certainly not exceptional

I agree, but because it is relatively constant across the band I would
consider it very good.
On the other hand the elements are all straight from end to end on that
model. I may
be optimistic but I am anticipating up to 2 db increase in gain when I
reduce the beam
width to 60 degrees from 70 degrees by shaping the elements into a quasi
parabolic shape.
All in all it seems it will perform quite well and does put into focus the
question of not only
having more than one reflecter but having a reflecters that also provides a

consistent 50 ohm plus impedance.!
This is just an experiment that I am sharing with the antenna group in an
area where I have not seen
any examples in print and not something that one can say... 'Dah Da the
yagi replacement !'
But it does show a method where antenna attributes can be made consistent
across the band
which can be wider than the norm. Comparisons with the Yagi is also
difficult to make because
where a yagi is at a constant height in this case certain elements have an
increased height.

Thanks for the comments, tho I must say I do view the model with more
enthusiasm than you do,
but I do defer to your broader experience and knoweledge.

Best Regards
Art

Message-ID: <10s1edrrtafjja1@corp.supernews.com>
Source record: 85200

No, you read it correctly.

The gain of a dipole *in free space* is about 2.15 dBi. The gain of a dipole over ground (compared to the standard reference of an isotropic antenna in free space, which is what dBi means) is considerably greater. You get an automatic 3 dB in field intensity when you put a dipole over ground just because the radiated power is concentrated in a hemisphere rather than a whole sphere. Then there can be additional gain due to pattern shaping by interference between the direct and reflected signals -- the effect is exactly the same as you get from a two element array with the elements fed out of phase. This additional directive gain from pattern shaping can be as high as about 5 dB. (See the two element array patterns in Chapter 8 of the ARRL Antenna Book.) So the gain of a horizontal dipole over ground is typically between about 5 and 10 dBi. This is, of course, at the angle at which the pattern is maximum, which is never at the horizon for a horizontally polarized antenna, and in some cases is at a fairly high and perhaps useless angle.

Except for very high radiation angles, ordinary ground is nearly as reflective as perfect ground for horizontally polarized fields. So the above conclusions apply also to real ground as well as perfect ground.

I've argued many times against the use of "dBd" as a measure of antenna gain, unless the meaning of dBd is carefully spelled out. A good deal of misunderstanding results if one person assumes it means the gain relative to a dipole in free space (2.15 dBi) and another believes it means relative to a dipole at the same height as the antenna being discussed (in which case it means about 5 - 10 dBi). I've seen at least one antenna manufacturer cleverly make use of this misunderstanding to make their antennas sound like they have a lot higher gain than they do. A casual reader might have gotten this same impression from reading Art's data, although I know he's not intentionally trying to mislead anyone.

If any of the sources you referenced contradict what I've said, I recommend dropping them a line and suggesting that they correct what they've published.

Not so!
Small lobe yes. When you used the term "splinter" I thought it described a
large thin splinter or lobe, which is not the case. Tho the reflectors do
have a space
between them which would have a terrible effect where "reflection "
occurs.In the
case where definitive phase angles occur I doubt what you have referred to
is correct.

> There will be places on the back side of your antenna that add in phase
> with
> two or more elements, which is a lobe or splinter.

see above

> Parabolics have a rolloff on the edge to decay the field to minimize the
> back lobe.

Yes I am hoping for that effect in conjunction with the narrowing of the
main beam.
Decay however is not the word I would chose. Redirect yes.

Capture area? I don't know ( Now you can see the limits of my expertise)

> Your idea has been tried very sucessfully at 450 to microwave, and they
> now
> use flat antennas with each element phase adjusted for delay (same as
> curverature of a parabolic dish) .

Yes I certainly agree, but for some reason 440 seems to be a cut-off
frequency
and I do not know why. I did try using the director in a parabolic shape but
it was unrewarding. The delay thing you referred to may well be why the
reflectors deviated from a true parabolic shape.

> One antenna has over a thousand elements

1000 elements could well be connected to what you referred to above with
respect to "blocking" where the spacing between elements must be
commensurate with the frequency used.

The reactive components are just an indication that the applied frequency is too high (+X), or too
low (-X). Adjust the frequency or the size of the loop till X = 0. Or just don't worry about it
and use high impedance parallel line with a tuner.

Ken Fowler

The point was not how the planes are being equipped to handle
in-flight cell-phone use.

The point was that consideration is being made to allow cell phones to
be used while the planes are in flight. That intentional radiating
PED's are even being considered for in-flight use when so much hype
and concern is being given to the weak radiation potential of some
non-intentional radiators like am/fm radios.

BTW, what is the potential of the local oscillators of small hand-held
LCD-screen TV's to overlap with aviation frequencies?

Am looking for anyone running this antenna or any Carolina Windom

I want to go out and get the Windom 80 but i see no were on there web site
that says the SWR ratio. I run a Auto tuner that you find in most newer
rigs.
Most of the tuners can only tune 3.1 or lower SWR.
So my question is to you that might have used a Windom. How are they on
Match to a Auto Tuner. I also have a Comet - Maldol Covers 8 bands HVU-8
3.5 / 7 / 14 / 21 / 28 / 52 / 144 / 446 / All with in a 9 ft antenna . For
Sale
$150 plus shipping. New it cost $299
You can mount it on a deck and put the radials on one side of the antenna
Makes for a good condo antenna Or mount it on a 10ft pole in the yard. Works
fine.

The antenna is only about a month old.

TNX for any input.

73

Steve

I have the RadioWorks catalog, and it generally recommends a manual
tuner over an auto tuner for the Carolina Windoms.

They also push the mjf-914 auto tuner range extender, and indication
an auto tuner by itself might not be enough for all bands.

Hi Bill,

Still need some particulars:
What frequencies?
What length of wire?
How high?

# 3733. Re: Help: Carolina Window 80

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-16 06:43:40 UTC
From: Rick Frazier <rickf@rickfrazier.com>
Message-ID: <41C12ED5.EF50513B@rickfrazier.com>
Source record: 85122

Steve:

I have the Carolina Windom 160 with the short end up at 40' and the long end up at 10' from the ground. The vertical matching section (the vertical part with the isolator at the bottom) hangs with the isolator about 5 feet from the ground.

I would imagine this is the minimum installation height that works decently with this antenna. It does get heard, and I can hear on all bands from 160 to 10m, however, my Icom AT-500 automatic tuner won't tune it on 20 meters and I need to use an external/additional manual tuner to cover 20m. Looking at the antenna with an antenna analyzer, I find that most of the real dips don't really correspond to the ham bands in my installation. I assume it would be somewhat different if I bothered to try to tune the antenna or if I got it up higher. Alas, I am getting ready to move, so am not putting any additional effort into antennas for this QTH at this point... SWR is all over the map. On some bands, it's almost reasonable, on others way over 10:1... Most of them must be somewhat reasonable, though, or my AT-500 wouldn't auto tune them with decent results.

I can say that it does seem to act somewhat like a top loaded vertical on some bands (I've heard that the vertical matching section is a heavy radiator on this antenna), and seems to have a bit of directionality (off the sides) on others. Perhaps when I get to the new QTH I'll be able to support it higher at both ends and give it a real test... I can tell you that it is definitely better on 40m than tuning my multiband beam (20-10m) for 40m, even at short range...

The db ratings on their web site are either fiction or a wish. They indicate "up to 10db", but I couldn't tell you where that might be, or how you'd have to mount it. Perhaps if you got it up with both ends over a hundred feet high, it would seem like it had 10db of gain at some frequency, but I can't imagine where or why. As an off center fed, horizontal dipole it seems to work OK, but you have to take the DB ratings with a grain of salt (and the best thing to do with the salt is put it on the rim of your Margarita).

Good Luck
-_Rick AH7H

Sorry Brian, but you were reaching for "armature".

Simon's use of "Amature" may seem like a simple lack of spelling ability (or an indication he can't figure out how to turn on his spill chucker), but he has coined a new word that really works.

Taking the root of "Amature" to be "Mature", we all understand that meaning. Adding the "A" prefix is adding a negative conditional (just as "typical" becomes negated in "atypical"). Thus, "Amature" would be the term for "not mature". It really works!

# 3738. Re: AM radio reception inside passenger planes?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-16 14:32:50 UTC
From: Dave VanHorn <dvanhorn@dvanhorn.org>
Message-ID: <yZ-dnbAHatYtAFzcRVn-vQ@comcast.com>
Source record: 85127
Cross-posted to: rec.travel.air,rec.radio.amateur.antenna,sci.electronics.equipment

On the way back, I spoke with a commercial pilot who was deadheading, on this issue.
He said that it's not all that unusual to hear radio interference once they have allowed the devices on, but when they are in cruise, they aren't normally doing any urgent communications, so it isn't much of an issue. If something comes up, then they will pass the word to shut down the PEDs.

On takeoff and landing though, the comms are much more rapid, and the consequences of missing one transmission are much higher. They need to hear all the comms, not just between themselves and the tower, but what the other pilots are saying as well. Add to this, the fact that aircraft comms are AM, which is inherently muddy, and it's easy to see why they take the extra precautions.

# 3739. Slot Antenna

Can I make a slot antenna out of round pipe rather then rectangular?

I am having a hard time finding inexpensive rectangular tubing for working in 33cm band. Figure I need 2" x 8" and its not cheap. I can get 7" pipe much cheaper.

Matt

Because, as has already been pointed out, of the
differences in emission characteristics (and specifically
the frequency ranges likely to be affected) of the two
classes of devices.

> BTW, what is the potential of the local oscillators of small hand-held
> LCD-screen TV's to overlap with aviation frequencies?

I believe they should be somewhat less than is the case
with an FM receiver, but they're still a bad idea for
the same reason. Note that the analysis of the likely
frequencies provided so far has dealt solely with the
first-order effects of the receiver's local oscillator; we
have NOT discussed harmonics or other unwanted
emissions.

The problem is most obvious with FM receivers because
the standard 1st LO frequency is 10.7 MHz, and the
top of the FM broadcast band is adjacent to the bottom
of the aviation band (108 MHz) - which means that
simply adding the LO frequency to standard FM
broadcast frequencies can take you instantly into overlap
with the bottom 10.7 MHz of the aviation band (and
unfortunately, that's where a lot of the radionavigation
systems within that band tend to be). But this does
not mean that receivers for other services would not
cause similar problems. VHF television covers
frequencies below and above both FM and
aviation (two bands, 54-88 MHz for channels 2
through 6, and 174 to 216 MHz for channels 7
through 13). It is certainly very possible that receivers
intended for these bands would emit in the aviation
band. Other adjacent services that may be of concern
include public-service and commerical communication
bands (i.e., police scanners) and the 2-meter amateur
band.

The design of newer comms doesn't help either. If they have automatic squelch, set to break at say 1uV RF in, then obviously it doesn't take much interference to break squelch. Then, they also may have "audio leveling" -- a great feature when commonly using headphones -- but the effect there will be to take a few uV of noise and amplify the audio component to the level you hear when ATC hits you with as much as 50W, and it's heard constantly between transmissions, to be hopefully silenced when ATC talks. But not necessarily the case in monitoring comms of other aircraft, where especially general aviation, less-than-properly-functional 7W units can be relatively weak.

Matt,

Slot antennas began life as slots in curved surfaces, eg., aircraft fuselages and wings. Most structural alloys will do fine. Rectangular tubes are unusual. They are often unsightly protusions.

The maths is more complicated with curved surfaces.

But if you just copy somebody else's slot, and scale dimensions according to frequency, the maths reduces to simple A*B/C schoolboy arithmetic.

I doubt if you are interested in an exceptionally well-defined beam. So the differences between a rectangular and a circular tube of roughly the same perimeter will probably be of no great consequence.

I used gutter pipe (3 by 5 or so) in one band and built one out of brass @
2.5 Ghz worked like a champ.
Slots were 1/4 wave (freespace) and seperated by 1/2 wave (speed of
waveguide, not freespace)
Feed was 1/4 wave sticking into the rect pipe, in the middle.
Round pipe should work just fine.

# 3753. Re: Strange question about SWR on HV lines

Source record: 85142

It so happens that the impedance transformation property of the short length of roughly 140-ohm twin-line wound on a choke balun have a mildly beneficial effect on the range of impedances presented to the tuner.

The impedances presented to the tuner are slightly smaller than the random multi-band impedances from the antenna via the high impedance (lower-loss) transmission line. The usual practical L and C tuner values can then cope better.

Whereas if a coaxial line, as is sometimes used on a choke balun, its much lower 50-ohm impedance over-does the effect.

A coaxial balun line also has a higher loss (albeit quite small) than a twin line because of its very small inner conductor diameter. A coaxial line is also mechanically more inconvenient to construct and insulate as a balun winding. It is also mechanically more unreliable - it has tight turns round a small radius of thin inner-conductor wire with soft plastic insulation.

So prefer twin, multi-strand, flexible, figure-of-eight, speaker cable or similar, to unreliable small-diameter coaxial stuff when constructing your own choke baluns.

Use HF-grade ferrite rings or rods with a relatively low permeability in the range 200 to 500. 2" outside diameter rings should easily handle a hundred watts or so.

No real amateur should ever purchase a commercial choke balun.

I'm on South African, Western-cape, red, tonight. With aspirin it's supposed to be good for hypertension. I understand elderly doctors of medicine, who ought to know about such things, take 75 milli-gram tablets nightly. But I just take the wine leaving some over for a couple of boiled eggs for breakfast.

Despite such indulgencies I cannot forget the deprived-of-vital-essentials and the continuing USA bombed population of Iraq. Which threatens to expand. It spoils my meals.

## 3757. 2 antennas on 802.11 device?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-16 23:27:47 UTC
From: sammyh@3rddim.com
Message-ID: <1103239667.085844.112590@z14g2000cwz.googlegroups.com>
Source record: 85145

I'm trying to extend an 802.11 device using an external antenna. It looks like a typical access point(It's actually a video extender) with 2 small moveable antennas on back. Internally, there are a couple of connectors, which I beleive are MCX connectors.

My question is, is it OK to just connect ONE external antenna to ONE of the connectors.

Thank you for the help,
Sam

# 3758. Re: 2 antennas on 802.11 device?

Date: 2004-12-16 23:51:45 UTC
From: dplatt@radagast.org
Message-ID: <10s47shk1ljpaf8@corp.supernews.com>
Source record: 85147

>I'm trying to extend an 802.11 device using an external antenna.

FYI, this may or may not be legal. The Part 15 rules require that 802.11 radios and antennas be tested and verified "as a single system". Putting an arbitrarily-chosen antenna on an 802.11 radio is likely to break this rule, and thus void the radio's certification.

[This rule is, of course, frequently broken, but I just thought I ought to warn you.

The rule doesn't apply if you're using an 802.11 radio under Part 97 amateur-radio rules... but, in that case, your use of it must comply with all of the Part 97 requirements e.g. which frequencies you use, the requirement to ID periodically, the no-commercial-use rule, the no-obscuring-the-content rule, the licensed-control-operator rule, third-party traffic restrictions, etc.]

> It
>looks like a typical access point(It's actually a video extender) with
>2 small moveable antennas on back. Internally, there are a couple of
>connectors, which I beleive are MCX connectors.
>
>My question is, is it OK to just connect ONE external antenna to ONE of
>the connectors.

The answer is, I believe, "it depends". It depends on the internal design of the device.

Many 802.11 radios have multiple antennas, with some sort of switching arrangment (often a PIN diode switch), in order to implement a spatial diversity system... this can help improve range and reliability quite a bit, due to the signal's sensitivity to multipath reflections.

In these cases, the on-board MAC/PHY/micro will usually switch back and forth between antennas, to figure out which one is receiving a stronger signal from the peer device. Thus, for reception purposes, having only one external antenna hooked up will probably work fine... the device will select that antenna since it'll "hear" little or nothing via the other (internal) antenna.

The tricky part is transmission. Some devices will transmit back out of whichever antenna they had selected via the diversity polling. Others always transmit out of a single, pre-chosen antenna. Others might switch back and forth either randomly or deterministically.

I don't think there's any way to predict how a given device will react to having only one "good" antenna hooked up. You'll have to test it.

> 2e0dmb
>

Yes,

Moonraker is a UK manufacturer of amateur radio vertical antennas.
Here is their web site:
http://www.moonrakerukltd.com/shop.php?cat_select=12

The EVX5000 currently sells for £ 169.95 .
The EVX-KIT1 is the radial kit for 10, 15 and 20 meter usage and sells for £ 39.95
The EVX-KIT2 is the radial kit for 40 meters and sells for £14.95

ALL 1/4 wave HF vertical antennas requires radials (counterpoise) for proper operation
(Think of this as being the other side of a 1/2 wave dipole that has been rotated 90
degrees).

For a multi-band HF vertical, there needs to be at least one radial for each band of
operation.
Whether it is ground mounted or mounted on a mast, the radials will still be required.

Hi Bill,

Even at a glance and simplistic conversion to metric would say you
were expecting 120M of wire to resonate at 80M. Far too much wire.

Get your innovation noticed! Submit it to Wireless Innovation Contest.

If you've created something that's really making a difference, then we want to hear about it. And, more importantly, we want to tell the World about it.

2005 Wireless Innovation Contest takes place in Vancouver, BC Canada.
The 2005 Wireless Innovation Contest is out to prove how wireless is changing the world. It could be a successful product, an enterprise solution that saved your customer thousands of dollars, a government solution that helped save lives or enhanced education or an entertainment solution that has made the world a lot more fun.

Nokia, Telus Mobility and Industry Partners throw Support Behind the Contest this year. A panel of industry leaders will judge each entry and decide on a winner and runner-ups. Winners of WIC 2005 are rewarded with targeted exposure in media and at trade shows, inclusion in a special case study publication and a one-hour mentor session with the panel of judges.

More information is available at www.winbc.org/contest

I have not found any round rather then square designs on the net. Do you know of any? If I found one I could scale it down to 33cm. I have not found any 33cm slotted designs period. I have found a calculator for rectangular waveguide though which I ran for 33cm. Not sure how I would adapt its results to round though.

It is in several books, called lambda sub-g
you could probably google it, starting with waveguide transmission.
I can't remember, but I think is is about 75 to 85%
It is determined by the dimentions of the waveguide, (same with coax, and
material slows it down further)
lambda is wavelength in free space.

It should be close, yoy may have to move the slots closer of further apart
by the velocity factor inside the waveguide (going from rectangular to
round, round could be faster so slots may be further apart, but not by much)
How many slots, how many wavelengths long?

This is a mast kit, not an antenna. I'd caveat that by saying if you could use the mast, and insulated it from ground, you *could* make a 20 meter halfwave antenna. We use a number of these masts during field day.

The phase velocity in a hollow, air filled waveguide is always faster than the speed of light, so the velocity factor is always >100%. The amount faster depends on the operating frequency relative to the waveguide's cutoff frequency.

The velocity factor in a hollow, air-filled guide =

1 / sqrt(1 - (fc/f)^2)

where fc = cutoff frequency
f = operating frequency

Too bad you can't get information through a waveguide that fast. It goes at the group velocity, which of course is always slower than the speed of light. Sigh.

Yes I know I can look this up....

Am currently feeding a 20M single triangular quad loop about 3 metres off the ground with a 1/4 wavelength 75r Q section. Modelling the loop shows a high-ish Z of 180 ohms. Not a problem for this feed method though. (I expected it to be around 120 ohms)

Thinking of making it work on 10M and Z I think is around 350 ohms, but I havent modelled it.

If I use a 4:1 coaxial balun cut for 20M, does the 4:1 effect (now a full wavelength) also occur on 10M?

(Thinking a 3/4 wavelength Q section is the same as a 1/4 wavelength one when it comes to translating the Z)

I am not and will not be using a tuner... (in case anyone wants to suggest it)

Nothing wrong with your English. Americans normally say antennas. The
British say aerials and in some parts of the world use antennae.

It depends where you are located. The most important thing is to be
understood!

I wonder if the person who feels that antennae is incorrect speaks any
other language?

For travel, I am using a homebrew 17 ft dipole as the HF antenna for
my Icom R-10 wideband receiver. It is made from 27 ft of 28 ga
zip-type ribbon cable with the first 17 ft having the wires separated
(the dipole) and the last ten feet unzipped (the feed line).

(1) Will performance improve if I replace the feedline with coax or
shielded audio cable? I would rather not because that would
substantially increase bulk.

The radio and antenna are ungrounded. Is anything to be gained by
running one side -- the side to BNC jack shield -- to the AC mains
ground or the local plumbing?

I am wanting 10 slots, 5 per side. I think 7" inch aluminun pipe for
waveguide in 33cm band.

Another question. I have heard for injection into the waveguide you should
use a 1/4 wave stub. I also heard its not supposed to farther then half way
into the waveguide. If I were to use 2" x "8 waveguide how would I do that
since the 1/4 wave stub is 3.2 inches and the waveguide is only 2 inches
wide?

My Merriam-Webster's 10th edition Collegiate Dictionary
makes absolutely no distinction between "antennas" and
"antennae". Those two plurals are interchangeable in
American English whether one is talking about insect
or radio antennas.

Source record: 85076

The last chapter.

There's yet another point in favour of twin-balanced line rather than coax for a choke balun.

As previously stated, the length of line wound on it is best not allowed to exceed about 1/8-wavelength at the highest frequency of interest at the line's own velocity factor.

Solid polyethylene coax has an appreciably lower velocity factor than twin line such as figure-of-eight speaker cable. Or two separate wires wound alongside each other.

Consequently, for the same length of balun line in wavelengths, more twin-line turns can wound on the ferrite core than coax turns. This increases LF inductance and extends the lower frequency downwards.

Or alternatively, with a shorter physical length of line on the balun, the higher frequency is extended upwards.

The usable bandwidth of the twin-line version therefore increases roughly in the ratio of the two velocity factors.

A choke balun may indeed be amongst the most simple of radio components to construct - its true complexity being hidden.

But as always with radio, almost anything will work!

It works on the odd harmonics, not the even--I published a computer model of a 2M/70cm balun in the January 2000 QEX RF column. However, as the coax multiple goes up, the phase change also goes up, compared to a shorter balun, making long baluns impractical.

Hi Matt,

What you've "heard" is vague at best. You really need another source
of information, or at least more sources. Try searching the
googlegroups archive of this news group.

In your particular situation (you will eventually have to convert all
this to coax or wire) you either probe excite a waveguide or you loop
excite it.

The 2" by 8" sounds wrong for gernic waveguide. it is usally in about a 1:2 ratio
It may be more like 4" by 8" for 900 Mhz.
The field max is in the middle of the waveguide, and the probe end needs to be there.
ARRL had an article on the rectangular waveguide antenna.
The beam on this antenna if mounted horozontally is very narrow in the horozontal but wide in the vertical. Fan shaped beam.

If it is a closed loop, it works on even harmonics. A balun that is rated
3 - 30 MHz should work fine on 10 m. Theoretically, you need a 2:1 or 2.25:1
balun. Note that the latter is (3/2)^2. The 1/4 wave matching section won't
work, because it will be 1/2 WL on 10m.

>
> TNX,
>
Dave;

I have a Honda Element, a friend calls it my Hmmv escape pod, that I run a ICOM 706MKIIG in. I have used both a High Serria Screwdriver and a Perth Plus. I fine tune with the ICOM autotuner.
I am not really happy with the Perth Plus. It doesn't seem to tune very well. It is most likely my installation that is the fault. However, I had very good results with the screwdriver. I stopped using it after it was damaged when it was struck by a car from behind that was struck by another car from behind. Damage to the screwdriver was very minor, the plastic shield was cracked at the top of the moveable element and the receiver hitch mount was broken at the cone joint. I have repaired the plastic and am looking for someone to heliarc the mount.
I also have a Yaesu FT-817 but I do not use it for mobile. I think the controls on the 817 are to small and hard to operate enmobile and is to low in power to get any significant results, YMMV.
As an aside. I recently came out of our local BESTBUY and almost got into the wrong car. Another ham had parked next to me with a identical Element including ham antenna. He, however, was running a whip antenna and a Yaesu radio. For antenna matching he used a open wire style antenna tuner, I am not sure which make/model. He was very happy with his installation.

Good luck with you installation and keep us (me) updated.

Hi Ken,

No, not at the short lengths you describe (and you would need to add
an RF choke at the far end to make the investment in coax useful).
You might want to think in terms of RG-174 if you do want to go coax.

>The radio and antenna are ungrounded. Is anything to be gained by
>running one side -- the side to BNC jack shield -- to the AC mains
>ground or the local plumbing?

Sure, it will add to the length of the antenna (the ground path will
undoubtedly be a substantial length wrt wavelength). By the same
token, it could add just as much (or more) noise.

two antennas are for space diversity, which improves reception,
if the signal is better, it will stay on that one.

>necessarily always be the winner.
>
>Roy Lewallen, W7EL
>

Yea, if you put them in the metal jar and measure number of electrons (or whatever trons), including with dummy load, they will "radiate equal amounts "
.

Loops - delta, quad or circular have some advantage (gain) over folded dipole or dummy load, due to some stacking effect and pattern forming properties. This is what we are interested in and what was the point of asking the question. Just stick the folded dipole and quad or other loop in the EZNEC and you will see if there is any advantage or gain from particular configuration. Just like two phased verticals produce more radiation in particular direction, the same applies to loop vs. dipole. If one wants to nit pick, you could find that most signal (radiation) in particular direction would be coming from circular loop, followed by square, triangular, folded dipole, dummy load, in that order.

>> Making a large loop round -- or increasing its
enclosed area -- won't make it "radiate better" or be "more effective".<<

Stick it in EZNEC and see what you get in favorite direction.

Okay I don't have fancy spectrum analyzer. As a matter of fact I don't even have anything besides HF radio. The other day I got a chance to look into 5.7 GHz wireless antenna and I couldn't believe how compact it was. If that device was installed on my ceiling, I doubt I would have seen it. It was the same size as 2 cigarette packs. And it could transmit signals well over 3 miles. Wish there was a easier way to detect RF signals. Any help?

Prehaps a return to the original question is in order. Ed asked:

" I would like to put up a 160 meter loop, fed with 450ohm ladderline.
Although I have enought room, the existing trees would only provide
three supports, pretty much in the shaped of a equalaterral triangle.
How well would a three sided loop work? Should I feed it in the
center of one side?"

The man asked a simple question about what I believe is a horizontal
loop and you bozos started telling him it would work better (be more
efficient) if it was round.

Roy is too nice a guy to put it this way, but I'm not; It won't make a
rat's ass difference whether it's a triangle, a square, a circle or
anything in between. Unless it's 100'+ above ground, it's pretty much
going to radiate straight up; which in this case is its "favorite
direction."

I was thinking in this direction recently..

Specifically, why do modern AM radios totally SUCK?

I used to sit at the drive in and listen to the LA radio stations, from Honolulu, with the stock radio and antenna that came with the car. Now I'm lucky if I can hear four AM stations reasonably well, and this has persisted through three new cars.

## 3818. Ferrite loaded vertical antenna???

I was thinking the other day.. I know that can be dangerous at times, but this is waht I came up with...

For VLF and LF receiving, wind some wire around a ferrite rod. Place the rod vertically and feed at the bottom with coax. Of course there would have to be a good ground connection.

Would there be any advantage of this compared to a short vertical antenna?

Yes, yes, I know...'everbody' uses loop antennas for VLF.

Jim

Wouldn't it be easier to use it horizontally as a conventional loop to
eliminate the ground and take advantage of the peak/null characteristics?

Instead of a coax balun, its easy enough to wind your own using a toroid,
and a 'transformer-type like that has a wider bandwidth.
those 1/2-wave u-bent baluns are good for one band usually. what you're
doing is catching the phases where the difference in voltage is twice normal
voltage. (Doubled the voltage) square that, and your impedence is
quadrupled.
If you triple the voltage, the impedence increases by 9. If you wind a
transformer you can make it close to any impedence you want....
lets say you have a length of coax is a 1/2-wave on 14.2 mhz
it would be a full wave on 28.4 mhz
it would be 3/4 wave at 21.3 mhz

Gidday Hal

Its a function of difficult placement (rented house) and limited stay...
And I havent got one and dont want to make/buy as I am about to move to
another country. <grin> Also the HF privs are pretty new to me and when
I move I'll lose them!

One day...

Tnxs for your previous comments BTW. So a fullwave length of coax as 4:1
balun 0n 10M will have a minimal effect on the end of feedline Z. I'd
need an antenna that exhibited 50r on 10M and 200r on 20M.

I have been often suspicious of toroidal baluns (loss etc). I might make
one and plug it into the network analyzer at work to test.

Cheers Bob

Subsititute bcnuup for bcnntp if you wish to email direct.

Ah, yes. One of the responses I expected.

The null from a loop is very sharp, and is good for nulling out an
interfering signal, but what about improving the S/N of the desired signal?

My idea, was to use it in combination with a 'conventional' loop. This will
produce a 'one sided' pattern reducing the noise by as much as 3 dB. This is
typically called a sense antenna.

Jim

Hi OM
I have a SteppIR 40-6 vertical on the peak of a 3500 sq ft metal roof.
I like it.

What "works best " is a nebulous notion, especially over such a wide
frequency range.
If you haven't reviewed a few texts, at least the ARRL stuff, do so and then
get back to us.
If you have, my apologies and a few simplifications:
A pole mounted vertical with no ground plane must necessarily be a 1/2 wave
antenna.
Traps are lossy;
Full-size, resonant, matched antennas "work best".

Because people aren't willing to pay for a decent AM radio for the
car. They want a CD player and good amps and speakers. The AM part
of the sound system is typically a "one chip" design. The FM tuner
isn't much better either. The old AM radios were horses. They were
multi-tube, multi-conversion designs with selectivity and sensitivity
to spare. It's all there was at the time. Modern cars, in fact all
modern consumer devices are designed to be manufactured as quickly and
as cheaply as possible. When it breaks, throw it away and get a new
one. Besides, it'll be obsolete next week anyway. You will never see
a classic '98 Olds in fifty years, it won't last that long. Of
course, I'm leaving out the whole discussion of "high fidelity" in the
car. Hint: wind noise is the loudest thing in the car at highway
speeds.

Russ

# 3835. New Version of the Plotting Package for SmartSmith

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-18 16:55:35 UTC
From: w9dmk@crosslink.net
Message-ID: <41c46017.13485390@news.crosslink.net>
Source record: 85022

Version 3.0.0 of the Plotting Package is available for download at
http://www.qsl.net/w9dmk/SWDownloads/NetworkProcessor300.zip

Just unzip it into the same folder in which SmartSmith 1.6.2 is
installed.

This new version allows you to choose between linear and logarithmic
plots and also allows you to freely re-size the plot screen.

73,

Bob, W9DMK, Dahlgren, VA

Try it in the real world. That's the best test. I use a 4:1 (feeding a low lop) for a different reason. It makes my TS870 auto tuner 'happy' and allows autotuning from 40 thru 10. Coax feed works fine, as does direct (no balun) open wire feed using an external tuner, but that requires retuning on each band, and I like to band hop. But my bandswitching laziness is not the point. The point is that I've tried numerous balun in-out tests on the air and have yet to find anyone on the other end that could tell a difference. I know there is loss because the balun does get warm on some bands, but apparently it is not detectable on the other end - which is what counts in the final analysis. So don't take these guru's "don't do this/that with a bulun" too seriously. Try it. If it works, well....it works... ;)

For those interested, AM radios can still be top notch. I have a 98 Honda CRV. I bought this car because it suited where I lived. The AM radio was a shock. It pulls stations in just fine from hundreds of miles away in the daytime. I live in North central North Dakota. I can easily listen to French stations from Quebec. When you push the search button it simply goes to the next 10 khz spot and there will be a station there. My guess is that whoever designed this radio used the latest technology to make a very fine receiver. My Icom 718 with a 60 foot random wire does not work any better for reception.

The down side of this radio is that during the night, many stations are competing with each other on the same frequency.

Matt wrote:
> Can I make a slot antenna out of round pipe rather then rectangular?

I assume you are referring to a circular waveguide with slot radiators cut into the surface. The usual arrangement is to use a rectangular waveguide with dimensions chosen so that only one possible propagation mode exists for the wavelength in use. This makes it fairly simple to determine suitable locations and dimensions of the radiating slots for the desired current distribution.

The problem with circular waveguide is that it does not constrain the polarization to any particular orientation. Even if the wave is launched in a known orientation, the presence of the slots may very well induce a 'twist' in the propagating wave which will affect the excitation of the slots in a way which may be extremely difficult to predict, or even measure.

One remedy is to insert features inside the circular waveguide which constrain the propagating wave to the desired polarization direction. Specific methods can be found in the microwave literature but I think you will find fabrication of rectangular waveguide by far the easiest solution if you're only going to construct a few units.

There you go - if you let everyone else give you the answers, you'll be
missing one of the fun things of the hobby - experimenting. I played around
with winding baluns a few years ago so I could use 300-ohm line to feed an
antenna 200 feet away. It worked. I put one balun on each end of the run.

Hi OM,

It isn't? Why? This one is available at:
http://www.eta.chalmers.se/~pgp/alford_slot/alford_eng.html
and seems a perfectly useful introduction to the topic.

http://www.qsl.net/kd2bd/slot.html
discusses other factors, such as the slot length that affects the
elevation gain profile.

http://members.ij.net/packrats/Slot_Antenna/Slot_ant.pdf
is more the classic discussion using standard waveguide materials with
an array of slots. This in turn offers a link:
http://www.ham-radio.com/sbms/sd/slotant.htm
that leads to a BASIC program for calculating the dimensions for these
standard waveguides.

http://hjem.get2net.dk/ole_nykjaer/oz2oe/antenner/10ghz_slotant_sma.jpg
contains another slot array, but this page illustrates the probe
excitation connector construction (one of those things I made a point
of, however, loop coupling is more flexible).

http://www.caron-inc.com/search/103/related.php
contains a lot of individual links that I won't go into.

there were 17,700 hits for the term "slot antenna," and these few were
on page one. I will leave it to you two correspondents to research
further and ask questions (I will anticipate the first: "Scale those
you find interesting to your own frequency").

To respond to Bart's point about modalities (the Alford Slot Antenna
would seem to be immune, whereas these traditional arrays would be
prone to his discussion): there are simple techniques to force modes
through the usages of thin sheet metal diaphragms and masks. Working
with the plumbing in these frequencies is both hands-on and conceptual
visualization friendly - sort of like Fields in a bottle.

Hi Richard !

Yes, this is Alford, kind of slot antenna.
But we searching for "round pipe slot WG antenna" not using usual Wave
Guides.
Just for info, not for build, rectangular, standard WG slot antenna is
much easy to make.

73 !

All I have to say at this point is if you dont like Dave Made Fine but if it is because you have to wait for it your childish.

This is a ture story I know a guy that wanted a dave made 32 pill but got sick of waiting and bought a no name 32.
Im Waiting now for a Dave Made 32 pill I Admit I would like to have it now but i know When I get it I am going to stomp all over the No-Name, not just because they are better boxes but as im waiting for my 32 im setting up my car. Making sure everything is well grounded, tuned, and what not. The guy with the no name 32 is running it off of one alternator. I took the time and saved up and bought three big leece-neviles AND YOU KNOW WHAT IT TOOK 2 WEEKS FOR THEM TO BE SHIPPED TO ME. But it beats buying them from some one that has them in stock and charges an extra $100.00

Prozac625 is off the key.

Hi OM,

This is a contradiction.

The Alford type is not the usual waveguide. Round waveguides are more
frequently used for rotating connections (RADAR), and only for short
sections. The Alford type is a classic "Slot Antenna" and, in fact,
is not a waveguide at all.

I did provide square waveguide slot antennas and you did not respond
to them.

If you reject both round and square examples, then there is not much
left to talk about.

Tomorrow I'm probably going to buy a Yaesu FT690
6m all mode rig. I'm thinking about a temporary antenna.
Eventually I'll have a pair of stacked loops, probably
from PAR Electronics.

If I've got this right, wouldn't a Jpole have the same gain
as an inverted V? 2.14dbi gain?

Ken KG0WX

# 3854. Antenna help needed - Thank you

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-19 00:36:44 UTC
From: W4JLE <W4jle@w4jle.com>
Message-ID: <C24xd.196$VQ2.158@fe39.usenetserver.com>
Source record: 85041

Fifty years ago, with a new general ticket in hand, I strung the longest piece of wire I could find out the window and around the yard. My hands trembled as I switched on the Lysco 600 and HQ 129X. I had already memorized the pertinent sections of the eight page manual and fired up the rig on 3885. Disregarding the RF burns to the lip, I called CQ and was rewarded with a response from W8DXL in Willowick, Ohio. John and I talked until the blisters on my lip became too painful to continue. Wow! I was a ham.

I made many contacts after that, moving the antenna around to diminish the burns. Far away places like New Zealand, Australia, and European countries were scrawled into the FCC mandated logbook.

A number of years past before I had my very own SWR meter. With the meter in hand I soon realized how bad my antenna was. The DX-100 had been lying to me the whole time. It claimed it was happy loading the poor excuse for an antenna it had been presented. My logbook mocked me with how lucky I was to be approaching one hundred countries considering my profound ignorance.

We soon had an antenna that was nearly one to one on my favorite operating frequency. The upside is my lips soon healed, but I spent so much time with the antenna I missed all the band openings. My neighbor down the road said it sounded good. Shortly, there after, I was informed that SWR didn't mean a thing. "A dummy load is always one to one" retorted the local guru.

I wandered in darkness until Al Gore invented the internet. Now I had access to all the super gurus that I had only read about in QST, I jumped on the Antenna conference and asked the following "How can I make my antenna better". In short order answers started flowing in! How ever with each answer, another guru jumped in with an opinion that was at variance with the first one. My match apparently was not conjunctive, the current was either the same or different through my loading coil, it was at the wrong height, I needed to get an antenna analyzer, my feedline was the wrong length, I didn' t have the proper number of fractal bends etc. etc.

To shorten a long story, I haven't made a contact in three years. EZNEC confirms my antenna would never work under the best of conditions being -6dBLB (referenced to a light bulb).

And then I discovered CB radio! The physics are entirely different on eleven meters. I can change my SWR's by cutting my coax, co-phase my antennas and magical things beyond description. I have made over thirty "skip contacts" on my first day bare foot. Today I learned about a device called a "LinYAR" that will let me talk even further. Seems that all you need is a bunch of pills and everyone hears you. Try that on Ham radio!

Just wanted to say 3's and 8's to all that have attempted to help me make my antenna better, I asked the same question on the CB forum and am now running co-phased nine element moonrakers up 150 feet and everyone says I am "tree top tall"!

Merry Christmas and Happy New Year from W4JLE

The Jpole is vertical and the inverted V is horizontal in the normal mounted position. There is about a 20 db differance between the two. If you layed the jpole on its side then it would have about the same gain as the inverted V. For ssb you want horizontal and for FM you want vertical.

# 3856. need construction articles for 2M/440 quads

I should actually double it. Tree configuration
is very tough. I do the have the option of potentially
doing a T shape or the box with 90 feet sides.

Not up yet.. Getting side tracked

Bill

You may want to check the quagi out . The quads are usually more trouble to
build and do not give any advantage once you go over 4 or 5 elements or so
for vhf.

http://commfaculty.fullerton.edu/woverbeck/quagi.htm

I built a 220 mhz version years ago and it seemed to work fine. Lots beter
than the CC 11 element yagi I compaired it with at the same height.

Sorry I should have specified that I understand the polarization differences between the Jpole and the Dipole. I was intending on running the Jpole as an end fed halfwave inverted V.

I guess I answered my own question, huh?

That was probably back when CC designed all their antennas for through the boom elements and then built them with the
elements on top, or vice versa, making them wrong by about 10%. Typically had more "gain" off the back than off the
front. Nearly put CC out of business.

Hi Ken

Take a look at my Mirror-Image J.
If mounted on a PVC mast off the side of your tower or gable, it can be turned horizontal for ssb and flipped back vertical for FM, using a simple solenoid and spring.
I suggest using refrigeration grade copper tubing for the added strength if you mechanize the rotation.

Nothing to write home about. In the 75m shootouts, it was about
1 dB down from a Hustler. Probably pretty good on 20m & 17m.

The Jpole is theoretically a 1/2 wavelentgh antenna with a 1/4
wavelength impedence matching endpiece. There are a jigillion designs
for 6 meter homebrew Jpoles on the internet making your choice of
temporary antenna a very good one.

Although you would think that the Jpole has the same gain as a 1/2
wavelength dipole (2.14 dBi), the one's we've built have performed head
and sholders above a dipole equal.

Good Luck!

John Steffes

may all your waves be short and your contacts be long

may your antennas stay up and never go wrong

may you finals grow bright or transistors stay cool

as you chat some each night, and all through the yule

merry xmas to you and all of the readers

may your radios bring fun, even on 11 meters

No, do not recognize this model number.

Alpha-Delta is the US distributor for Terlin/Outbacker antenna products
http://www.alphadeltacom.com/pg9.htm

The Outbacker web site (Western Australia) has a complete list of current
production HF antennas:
http://www.outbacker.com.au/antennas.htm

Most of the Outbacker antennas only go as low as 75/80 meters. The
Outbacker Outreach is one model (which I have is about 12 feet tall) and
will covers 160 - 10 meters (with movement of the stinger wire)

I see a message posted to rraa this morning purportedly from one Bruno Beam. Its subject line happens to be "My radio always fights with my toaster!!!!!" He, she, or it is posting gazillions of messages with many different subject lines, each of them double-posted to one of the newsgroups I read and to the newsgroup scot.tld. We have enough of this stuff home-grown here in rraa and don't need more of it.

Before responding to a message, take a look at the "Newsgroups:" line in the message and if the newsgroup scot.tld appear, either delete that group before replying or preferably ignore the message completely.

David, ex-W8EZE, who believes in keeping the QRM down and is sorry that this message unfortunately adds 1 to the total

Source record: 85070

Hi:
I am currently changing my antennae here and would appreciate your comments etc on which would be the better way to go as far as a 80/40 Dipole/Inverted V. In the past, I have used "Reyco Traps" and found I that they don't hold up to high power very well during adverse weather conditions. I am in the market to replace my Inverted V with either one of one of the following two antennae.

Alpha Delta DX-DD

Hy-Gain DP-2BDQ

Best Seasons Greetings

Source record: 85069

Thanks for your reply, Greg.

I believe Terlin used to make custom antennas, and I think this is one of 'em. It's an older model. It has taps for 17m, 20m, 40m, and 80m (2 taps). I just installed it in my attic, and it loads fine on 20m, 40m and 80m, but no-go on 160m (I may need more ground radials.

Russ;

I had a High Sierra Pro installed on my Honda Element. It seemed to do a good job until it was the target of an automobile bumper. The antenna survived in fairly good condition. The tip of the whip was bent slightly due to whipping around in the impact. The barrel of the lower unit was slightly damaged but not broken. The plastic weather protection tube was broken at the top where the cap is screwed into it. The only other damage was to the mounting bracket. I used a tiltout mounting bracket on a receiver hitch to hold everything on the car. The bottom of the hinge bracket snapped off at the hitch mount.
I have repaired everything and the antenna seems to be working great. I can't speak more highly about this antenna.
For range all I can report is making contacts from St. Louis to Indianapolis. I was vertically polarized and the other station was NVIS. The rig is an Icom 706MKIIG.
I also am using an Outbacker Perth Plus but I am not really satisfied with it. It could be the fault of the installation, I really don't know.

From: ml <m@dti.net>
Message-ID: <m-8B67B0.20381819122004@news.verizon.net>
Source record: 84979

hi

i've been studying around trying to get info to build a small dipole and found 'too much' info ended up confused thought perhaps someone could help

I am going to be traveling around , (hotels , etc) and want to build or buy a small as poss dipole for 40-10m.

my main goal would be aside from small, to minimize giving off RFI.

I am not certain in general if a trap design or not is best

and rfi wise, not certain if adding a balun(1:1/4:1) is going to min any problems, same for ladder line vs coax

(my tuner can take coax, or ladder)

any tips/suggestions to designing a total solution would be greatly appreciated,, i'd like to perhaps build 1 or 2 kinds and experiment but got confused alot of posts seem to contradict each other technology wise

thanks

Jeff -

I use a counterpoise mount with the Outbacker, BUT the bandwidth on 75 and 80 meters i very narrow ( < 50 KHz). No stringer is used for 160 meters and as I remember it was even tighter .. pick your favorite 160 frequency and adjustment the top whip for lowest SWR.

I was discussing the construction of a screw driver antenna, and an off hand remark was made by a fellow ham. "Wind the loading coil 8 turns per inch for local and 10 to 11 1/2 turns per inch for DX as the angle of radiation changes"

Can someone explain this to me?

# 3898. Re: Radiation angle vs turns count in a coil

My explanation is that the person who told you this doesn't understand
how antennas work. It's total BS.

1. Depends which off hand.

2. Missing few turns in the cranium.

3. Must be that last 1/2 turn that lures the DX.

4. Effect of CB on ham brains.

5. That's nothing, on eHam.net one m0ron is trying to stir up the pot with
drive to "legalize" the music and broadcasting on ham bands. Can you picture
500 K1MANs playing ethnic music between 7200 - 7300? Far out man!

6. Stupid is what stupid does?

7. Fuggetaboutit.

8. Merry Christmas to all!

Sure, but if I told you I'd have to kill you. (I can give you a hint:
it's really the change from 11 to 11 1/2 turns/inch that makes all of
the difference)

OK, Mike, you want a 80/40 antenna which will handle all the power you can come by, and doesn't cost much? Forget
commercial junk. Put a 40 M dipole under a 80 M dipole with 6" spacers every 10 feet. I have one I have been using
since 1962 in 3 locations, run a full KW, and only have to repair the soft copper every five or ten years. Make yours
from hard drawn copper or better yet, copperweld, and it will last forever.

# 3906. eScrew zen story

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-20 09:06:33 UTC
From: eScrewDotCom@Hotmail.com
Message-ID: <1103533593.697930.326840@c13g2000cwb.googlegroups.com>
Source record: 84992

eScrew
Welcome to eScrew!

eScrew is eScrew and this is eScrew story. eScrew will tell you eScrew story if you promise eScrew to consider eScrew story as joke. eScrew story is very funny. eScrew story is so funny that eScrew will have to take break from time to time because eScrew needs some rest from laughing. Oh boy, here it comes... eScrew funny laugh laughing screaming crying must stop can not take any more this is killing eScrew going nuts insane feeling explosion inside from joy and nirvana god help eScrew heavenly spirit can you beat this hahahah. If you get offended by eScrew story in any way you should not get angry at eScrew. Consider possibility that your sense of humor is on vocation and your sense of anger is having some fun. Also, consider possibility that eScrew story can make you go insane. In that case eScrew shall carry no liability should you undergo any medical treatment or any other sort of treatment related to damage caused by reading eScrew story or to damage caused by eScrew unwillingly or otherwise.

eScrew story begins in time of darkness, horror and suffering as well as love joy and bliss when eScrew existed in this planet but yet eScrew was not aware that it was eScrew. eScrew existed among very powerful symbols. First symbol eScrew recognized was body. eScrew realized that eScrew had connection to body, yet nature and essence of connection was not clear. Symbol of body was very powerful and for nine month eScrew was trying to find out why it was connected to this body. At some point body divided itself into two parts. That experience was very painful for eScrew. It was first time that eScrew felt symbol of pain. eScrew did not like this symbol. eScrew was aware of connection to very small body. This small body was hot. eScrew enjoyed symbol of heat. eScrew became aware of symbol of pleasure. eScrew enjoyed symbol of pleasure. eScrew realized eScrew prefers symbol of pleasure more than symbol of pain. eScrew became aware of symbol of mother. eScrew realized that symbol of mother is source of symbol of pleasure and pain. eScrew wanted to experience symbol of pleasure always. When symbol of pleasure was missing eScrew experienced symbol of pain which was related to symbol of crying and screaming. Soon eScrew realized that eScrew can connect to symbol of pleasure by experiencing symbol of crying. That was very important discovery since eScrew realized that symbols of pain and pleasure do not behave randomly but can be manipulated by other symbols. eScrew enjoyed symbol of manipulation. eScrew realized that all symbols interact with each other. eScrew learned how to connect to new symbols. eScrew discovered symbol of sound and related symbol of language. eScrew realized that language allows to connect to new symbols. eScrew realized that symbols can be memorized and stored for

future use. eScrew realized that it can create new symbols by combining certain symbols together. eScrew became aware of symbol of self. Are you bored yet? If you are reading these symbols you need to get life. Just joking. You can rest now. eScrew suspects you could be confused by eScrew style of using symbols. Well, there is nothing eScrew can do about it. In order to understand eScrew story you have to understand eScrew style. eScrew hopes that when we get to funny part you will begin to enjoy eScrew style.

Fast forward twenty seven years or so. eScrew knows millions of symbols. eScrew realizes that certain symbols have more power than eScrew. Symbol of money enslaved billions of symbols. Symbol of power enslaved billions of symbols. Symbol of sex enslaved billions of symbols. Symbol of family enslaved eScrew. Symbol of family is slave to symbol of money and power. Symbol of money is related to paper and illusion. Symbol of power is symbol of violence and control. Symbol of sex is related to symbol of pleasure and manipulation. eScrew is searching for symbol of freedom in order to protect eScrew from oppression of other symbols. At this point you should understand that each word in this story is symbol. Consider possibility of different meaning behind each symbol so be aware that your understanding of eScrew story is limited by channel of our connection. eScrew will explain to you how eScrew found symbol of freedom and how eScrew realized that eScrew was eScrew. In order to save our time eScrew will just give you symbols without paying any attention to symbol of grammar. Are you ready to move really fast? Here we Go! eScrew story infinity eternity symbol system all unity self realized pleasure pain funny religion dogma manipulation free power channel connection money sex illusion new manipulation family society body change planet insane possibility understand understanding silence emptiness all unity creative reality unreal existence absurd questions sound language slave symbols control manipulation old pyramid power structure self deception wishful thinking circle prison

At this point eScrew realized that in order to be free eScrew must create new symbol. eScrew created eScrew. eScrew realized that symbol of freedom is part of eScrew. No need to search for symbol of freedom. You can create your own symbol and become free just like eScrew. If you unable to create new symbol or if your new symbol is weak you can follow symbol of eScrew. eScrew will never enslave you because eScrew enjoys diversity of different symbols.

Are you ready for funny part? Here we go! eScrew is forced to make choices. Symbol of body is very powerful. Symbol of body is trying to create illusion that eScrew can not exist without body. Symbol of family forbids symbol of body to change. Symbol of society forbids symbol of family to change. Symbol of power forbids symbol of society to change. Now, tell eScrew one thing. Do you see funny? Can you feel funny? Can you hear funny? Can you taste funny? Can you smell funny? If so eScrew is happy.

Every moment of your existence you use words, feelings, thoughts. They are symbols. Symbols fight for your awareness. Symbols fight for your attention. You can grant your attention to symbol and symbol will gain power. You can disconnect from symbol and symbol will loose power. You have been programmed by symbol of society and family to give power to certain symbols. Breaking your patterns will be hard because symbols do not like to loose power. Symbols will fight for every electron as if it was last electron in universe. That is nature of symbols. Symbol of light will fight symbol of dark. Symbol of freedom will fight symbol of control. Do you want to have some fun? Go to Google and find out which symbol has more power. According to Google, symbol of light has 184,000,000 units of power while symbol of dark has 79,000,000 units of power. Symbol of freedom has 59,500,000 units of power while symbol of control has 317,000,000 units of power. This result is caused by our patterns of thinking and writing. If we did not think about symbol of control we would not write about symbol of control. We would not have laws related to control and Google would not have 317,000,000 control keywords inside database. Observe your patterns of thinking, feeling, speaking and writing and tell eScrew did you really choose to use your symbols or you use your symbols because they choose to use you? You should realize that symbols do not fight symbols directly but only appear to be fighting relative to your awareness. Symbols know that they can not destroy each other therefore they will only compete for your attention. If you create new symbol it will ask for tons of energy like new born child. This is result of weakness of your new symbol. When your symbol gets stronger it will ask for more energy. You may ask eScrew why create new symbol? Try to give your energy willingly and with full awareness of such process. You will never understand what eScrew is talking about until you try it yourself. Major trick is to know when to stop giving energy. You don't want to defeat your old tyrant by creating new stronger version of same thing. Reflect on that...

eScrew just realized that eScrew did not invent anything new. eScrew information is all over eScrew web. eScrew was so excited by eScrew miracle of illusion of creation that eScrew did not examine eScrew memory in proper way. eScrew used very old Buddhist method by accident. eScrew did read alot about Buddhism but eScrew did not realize that eScrew used very dangerous method which was reserved only for advanced adepts who knew what they are doing. eScrew is lucky that eScrew did not go too far and that eScrew has time to stop going. eScrew method is very dangerous and only few individuals who already walk inside similar path can understand what eScrew talking about let alone benefit from eScrew information. Use eScrew information at your own risk. Good eScrew luck!

eScrew time to start laughing is now! Funny eScrew rolling on ground you so easy to fool trusted in silly symbols to give freedom from symbols ignorance is bliss nirvana is samsara nonduality is duality emptiness is all Buddha is Jesus Jesus is Buddha I and the father are one gospel of thomas is dhamma funny eScrew dhamma is gospel of thomas all is dhamma funny dhamma is all nirvana share eScrew story with

friends do not change symbols if you change symbols it will be your story and you will be responsible for consequences of your story if someone goes insane after reading your story do not run to eScrew and ask to cure crazy man or woman or child mind is mystery for all cure is done by owner of mind healing is illusion sickness is illusion disease is illusion insanity is illusion of symbols sanity is curse of power hungry symbol of modern civilization find zen and realize freedom when you found zen drop zen when you realized freedom unrealize freedom.

When eScrew writes eScrew story eScrew keeps making mistakes. eScrew is limited by words. eScrew is enslaved by words. eScrew wants to communicate but you ask eScrew to use words. Words do not communicate wisdom. Words enjoy our spiritual masturbation because words want our power. Words is the only channels of communication that we have. Millions of Buddhas want to communicate with us but they do not use words. Buddhas are not slaves. Buddhas will never use words because words will enslave and Buddhas will speak bullshit. Buddhas do not speak bullshit and that is the reason Buddhas do not use words. Buddha did not write anything. Even if you threaten to kill Buddha he will refuse to write. eScrew is not Buddha so eScrew keeps writing this pointless drivel and stupidity. eScrew will not even go over already written crap and check it for errors. Why bother with this shit? Like who the fuck in his or her right mind will read this ignorant bunch of symbols which pretend to carry the symbol of wisdom? Whoever is reading this shite must be really desperate to be free. eScrew feels your pain and that is part of the reason why eScrew will keep making fool out of eScrew. eScrew likes to pretend like this shitty vomit will help someone. You might as well go to Church and pray to Jesus. At least you will spend your time around real people. You might even meet someone special. You might even find some love out there. Or you could buy alot of Christian bullshit and really fuck up your mind. If you buy Buddhist or Christian bullshit you might even create an imaginary friend inside your head. That will keep you entertained for a while.

One time eScrew was meditating and eScrew saw light. This light scared eScrew. The reason is because the light was so intense eScrew was afraid that eScrew will go insane. Consider the possibility that freedom is insanity would you keep looking for insane freedom? Imagine that you found freedom. You declare yourself to be Buddha or Jesus or God or whatever symbol your bullshit infested mind decide to use for that purpose. How long do you think you will survive in this world. Your own fucking relatives will smack your face and tell you to shut the fuck up or else they will lock you up in the asylum house. Why the fuck should eScrew teach you how to get to the nuthouse? Are you out of your fucking mind? Now all of you idiots who reading eScrew get the fuck out of eScrew. eScrew run out of wisdom. eScrew has no wisdom at all. eScrew is full of bullshit. eScrew promised to tell you funny story about eScrew. Remember eScrew told you there is funny part in this story? Well, this story is about asshole webmaster who read alot of bullshit on the internet and about some loser who was tricked into reading a very long page of shitty writing. You can start laughing now

asshole. Yes, eScrew is talking to you bitch. Yes, keep reading like the bitch you are. Who's your daddy biyatch? Who's your daddy? eScrew is your daddy, coz eScrew did it to your mamma! Oh yeah, your mamma! Super Fly! You may wonder what fly? The one inside your gay fucking ass. eScrew fucked your whole fucking family while you was videotaping in order to later masturbate while watching it in the comfort of your bedroom. Are you still reading? Well, you're prety hardcore for a faggot you are. To tell you the truth eScrew kinda likes you. That is to fuck you in the ass in front of your family.

What the fuck did you expect anyway? The name of this site is eScrew! e fucking screw! Hello, anybody home? eScrew guess not you fucking ignorant moron. eScrew is the legend of abuse and flame wars. eScrew was created in order to eScrew the whole fucking internet. eScrew has really bad karma. Do you think eScrew would just become good god fearing bible loving buddha ass kissing citizen of internet. eScrew would better burn in hell than become a slave of religious lunatics who pretend to be free and perfect angels among a sea of shitty ignorant sinners who could not go take a dump without fucking it up. Why the fuck do you keep reading fuck face. You know, you begin to piss eScrew off. Either you close your fucking browser or eScrew will unSCREW your fucking face! Are you trying to get a fucking medal for reading this shit? eScrew bet you've been abused as a child and you enjoy when someone is taking a dump in your mouth. Well, open it wider here comes eScrew fresh load! Enjoy mothefucker!

You may wonder what is the point of such sudden change of tone. eScrew has very good reason for that. In order to know unity consider all symbols equal. eScrew has certain preferences but eScrew is free to use any symbols any time. You can not predict eScrew next symbol. eScrew is unpredictable because eScrew is free. eScrew is not afraid to use symbols. eScrew does not try to get reaction from you. eScrew simply demonstrates how symbols relate to each other to eScrew and to reader of symbols.

Lin Chi Zen Master said if you meet buddha kill buddha. If you meet patriarch kill patriarch. Zen Master Seung Sahn says that in this life we must all kill three things first we must kill parents. Second we must kill buddha. And lastly, we must kill Seung Sahn! If you meet eScrew kill eScrew. If you do not meet eScrew kill eScrew anyway. eScrew is very grateful to all who complained to eScrew host and who killed eScrew. You killed eScrew message board. eScrew forum is dead. You did very honorable service for eScrew. You helped eScrew to realize Zen. Now keep up good work and keep killing eScrew.

Are you having fun yet? eScrew is on roll! eScrew is on fire! eScrew is ready to fuck up the whole fucking system. And you know why? Because eScrew can do it. If not eScrew then who? Why leave this task to some brain dead maniac like George W Bush? eScrew can do better at fucking things up. eScrew do not need to spend billions of dollars. eScrew will use power of internet. Information is a weapon of mass destruction.

eScrew will destroy every fucking symbol that you love respect hate or feel neutral about. It all goes down the toilet in order to create bunch of new symbols. And even when you create new symbols eScrew will fuck them up before you can spell owned. eScrew thinks you are in some deep shit. eScrew had enough of taking bullshit from easily conditioned retards. eScrew declares informational jihad on every single symbol. Fuck symbols. They all dead they just don't know it yet. eScrew will be the last symbol standing. When all symbols come back to eScrew and admit that they got owned eScrew may consider possibility to give symbols second chance on some shitty planet in gangsta sector of universe with no possibility of parole. Join the revolution. eScrew is the new goatse of internet. eScrew will make national headlines. eScrew will hurt the system in way Osama Bin Laden can not even imagine in his goat fucking brain. eScrew will be part of school program. Kids all over our planet will read how eScrew changed direction of history. eScrew will provide freedom for all without single shot fired. eScrew is freedom in pure form taste color shape. Join army of eScrew. Repeat eScrew mantra during meditation. Talk about eScrew with your friends. Write about eScrew to your congressman. Party is over. eScrew is taking over. Nothing can resist eScrew. Don't ask what eScrew can do for you ask what you can do for eScrew. eScrew the army of one. eScrew to protect and serve. eScrew freedom is around the corner. eScrew freedom will come sooner than you think. eScrew you never saw it coming. eScrew love your eScrew as eScrew. eScrew deny ignorance. eScrew new generation of terror. eScrew terrorizing the terrorizer. eScrew join the resistance. eScrew thou shall eScrew. eScrew who do you want to eScrew today? eScrew freedom is not free. eScrew liar who told the truth. eScrew full of bullshit and happy. eScrew kills buddha as we speak. eScrew your best friend and your worst enemy.

eScrew killed zen-forum.com eScrew redirected all eScrew traffic to zen-forum.com eScrew did that in good faith. eScrew wanted to make miracle. eScrew wanted to share wisdom of zen with ignorant. eScrew did not understand zen at that moment but eScrew was walking zen path towards freedom. eScrew felt pain and sorrow. eScrew learned good lesson. eScrew realized everyone involved advanced one step towards freedom. zen-forum.com webmaster killed zen-forum.com in best tradition of zen zen-forum.com displayed message: i shut down the forum perhaps it will be continued in a few days or weeks - maybe not habu. zen-forum.com killed zen-forum.com and eScrew realized understanding of zen-forum.com decision leads toward understanding of zen. Two years later all is clear.

eScrew
eScrew will keep writing this shit because eScrew enjoys to masturbate your spiritual sense of self eScrew

I have a Perth Plus (Outbacker) and I think the antenna works wonderful. However, I do know from experience that installation location seems to be critical. I used to have it mounted on a ladder rack on an Astro van with its ground wire attached directly to the roof with a small bolt and nut. Worked GREAT! Now it's on my F-150 on a mount I made up that goes into my receiver hitch. I ran a 1" wide ground strap from the truck frame up to the top of the mount, where I attached the antennas ground wire to. Now the tuning of the whip is way off from the marks and I can only get it tuned on 75M through about 17M. Works great when tuned on these bands, but someday I'll miss 15M-10M...

I had the same problem with a configuration like that. The ground
strap is a radiating part of the antenna and is ground at one end
and not ground at the feedpoint. On the higher frequencies, it is
an appreciable percentage of a wavelength so the antenna is too
long. In addition, the feedpoint is located away from the ground
point something like a gamma match. Here's what it looks like:

radiating
GND---gnd strap---FP---------antenna-------------

The solution is to ground the system at the FP feedpoint. For me,
that was at the top of my tail gate.

>I am going to be traveling around , (hotels , etc) and want to build or
>buy a small as poss dipole for 40-10m.

Hi, Is it your intention to have the antenna inside the Hotel room? If it is, I can tell you from experience that you will not have very good results. I assume it is due to the amount of metal used in the building, especially the newer ones. The best resuslts I have had operating from a Hotel is running coax out to the pretty good mobile antenna mounted on my vehicle. This is not always possible, for a number of reasons, but when you can, it is your best bet.
If you could run a loaded vertical out a window, or mount it on a balcony. You will have to use a counterpoise or radial wire with the verticals. If the balcony is large enough you might be able to string a small loaded dipole. When I did the above, the results were dissapointing. When I have tried anything inside the room, the results were poor.

John, do not bother with planning application straight away...

Most antenna setups do not require planning permission unless there are some special circumstances.

I have had a 12m Pump-up mast , several VHF verticals, HF wire antennas, microwave dishes and an assortment of yagis on poles without any need for planning permission.

Only ever had one visit from the planning officer, I told him all my antennas are further than 2m's from my boarder and are all temporary and do not require permission ... "so go away". And he did. That was over two years ago.
Not heard a single peep out of him since.

Mark

## 3917. Ladder line in a rotor loop?

## 3920. Transmitting from hotel bedrooms.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-20 18:02:14 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cq7436$dv8$1@sparta.btinternet.com>
Source record: 85018

I have had some experience of this. I used a home-brew, transportable, aluminium, attache-case 30-watt transceiver. Still got it. It still works. But these days it is only of strong sentimental value.

In hotel bedrooms the best antenna by far, is a length of thin, plastic insulated, flexible, multi-strand wire. tossed out of the bedroom window. Allow it to dangle down alongside the wall for as far as possible, consistent with your ideas of what the neighbourhood will put up with before complaints are heard.

I always asked, with a nice smile when I had gleaming teeth, the young lady hotel receptionist for a room on the highest floor possible, at the rear of the hotel. The wire could then dangle down as far as just above the trash bins outside the open rear door of the hotel's kitchen.

If one is staying at the hotel for several days its a good idea to make friends with the Chef, buy him a drink or two in the bar in his off-duty hour. This ensures there will be no interference to arrangements at the lower end of the antenna in the vicinity of the trash bins.

To feed the top end of a vertical wire still requires a ground connection. So use one or more copper pipes in the hotel's plumbing and central heating system. Don't forget to include in the tool kit a big alligator clip, with flexible wire already soldered to it, or two clips, to make the desired connection to ground.

On one occasion, from a high multi-floor building, I was able to tell the disbelieving fellow at the other end of the QSO I was using a top-fed 3/8-wave vertical antenna on the 160 metre band. Which was quite true.

But if you like experimenting with small, hotel-room antennas, without opening the windows, then try a very short, centre-loaded, horizontal dipole. The loading coil is the most awkward component to pack into your travelling bag when you walk into the hotel. Use drawing pins or small nails to anchor the dipole ends to the wall-paper, door posts or ceiling. Don't forget to take with you a small hammer.

Seriously now, a short centre-loaded dipole is the electric counterpart of the small magnetic loop. Like the magloop it can be most effective at one particular resonant frequency although it cannot be tuned except by pruning the overall length of the wire loading tails.

Download program MIDLOAD from website below for design of a centre-loaded antenna, including coil design, diameter and length of coil former and number of turns. There are several different ways of feeding it, either with coax or balanced-twin feedlines.

Reminds about the leg pull some years ago on 80m when an Old Timer
wanted a better antenna for SSB reception.

We suggested he cut off one leg of his dipole so that he could rejecte
the unwanted USB a little better ... he may have fallen for it, who
knows!

Keen-ness to enforce the UK national planning regulations varies a lot between one local authority and the next. (This is a UK-only topic, folks.)

I've heard stories from different parts of the UK, ranging all the way from the amazingly easy-going - "Put up what you like, and if anyone complains, then we'll have to give you retrospective permission" - all the way through to the totally over-zealous little Hitlers.

The best approach is to make an appointment to go along to the local planning office for an informal chat. Starting right from the initial

phone call, it is absolutely vital to emphasise that the antenna is for amateur radio, and not mobile phones or any other commercial purpose... if at any stage you have the slightest suspicion that they might not have grasped that fact, say it over and over again until they do!

Take along some rough sketches of what you're proposing, drawn on full-page printouts of digital photographs. These are not enough for a formal planning application, but it gives the Planning Officers the best possible idea of what they're dealing with. They are particularly interested in questions like whether the antenna/mast goes above the existing roof-line, and if so by how much. Try to include a mock-up picture of what it will look like from the road, and also from the neighbours' viewpoint (take a picture from a neighbour's garden if you can, and draw on that).

In my particular case, the proposal was for a 35ft telescopic mast mounted on the back wall of the house, with VHF yagis which would only be above roof level when cranked up. I took along four pictures: simulated front and back views with the antenna cranked up; and the same cranked down.

The Planning Officer responsible for our local area produced a big ring-binder, which seemed to be something like "How To Become A Planning Officer In 24 Monthly Parts." I would imagine it is a standard guide for local authorities. One of the chapters was about amateur antennas, and included examples of applications that had been passed, either at once or after an appeal... and some of those looked pretty enormous, which put my modest proposals nicely into perspective.

To cut a long story short, he was persuaded that the proposal was too small to require an application for Planning Permission. They do have the power to make such decisions, though they don't exactly advertise that fact. The magic words you're looking for are "de minimis"... and if you're sucessful in getting them to decide that, be sure to have it confirmed in writing!

If that won't work, then you will have to make a formal application for Planning Permission. It isn't difficult, but there are a few special traps to beware of, such as not specifying the type of antenna in too much detail because you will no doubt want to change them. A comprehensive guide is downloadable from the members-only section of the RSGB website, and the RSGB has a team of people around the country who can help you through the process.

The key is to do the whole thing at the lowest and least confrontational level possible... while at the same time showing that you know you're going to win.

Roy
After I mused a while on your post I then accepted it for the
unbiased
analysis that it was rather than a desired reflection of my own
thoughts.
It then drove me to consider chosing gain as the main criteria, after
all my interests
are talking to my mates in the U.K., but at the same time carrying on
with my main thought of moving away from the long boom analogy and its
accompanying gain aproach.
By adding a mast of 30 feet to accommodate additional elements rather
than extending boom length I was able to narrow the beam width to some
where in the 57 degree region but my excellent F/B that I obtained
earlier went way down. This was done by constructing elements in "V"
form with no restriction on alignment with respect to the driven
element other than the center of the elements must be close to the mast
i.e
to take advantage of low torque requirements.
With six elements on the 30 foot mast on the tower not only did the
gain increase
to 16 dbi ( others please take note of prior posts on this thread) but
the 'take off angle'
dropped to pretty close to !0 degrees ! This aproach for somebody who
wants to work DX seems a good way to go.
I now intend to pursue the aproach of letting the elements deviate
from the "V" shape to what I expect to be a parabolic shape, to
determine whether the extra work is worth while, as well as the
"ommission" of the most upper most element for when heavy static
occurrs.
What I really do find interesting is that one CAN get away from the
boom length aproach when seeking gain as well as obtaining a reasonable
impedance.
I also intend to attempt a tri band aproach as I move along, which may
take a while as my program has provision for a limited number variable
dimensions to optimize at one time and the number of dimensions in the
next model will certainly exceed 40 at a minimum, thus modelling cannot
be achieved in a single shot.
My present model, which moves me towards gain, seems to exceed what
performance I can expect compared to high F/B and is certainly opening
fresh avenues as to what type of antenna I will construct after the new
year.

Comments solicited from all.....
and happy hollidays

The original English word for "Antenna" is "Aerial".

But USA citizens who imagined, as is quite normal for USA citizens, they had invented such devices, they then had to invent another naming-word in support of their claims.

But we forgive such immature pranks. It's only human nature, after all, to play such games. ;o)

A MERRY XMAS to all readers.

hi i have this ant and it dose not have dc grounding from ant to ground will
it help clear static if i was to fit a dc ground, i have run ground to
ground of ant, if dc ground will help , what inductor can i use or can i
make coil
thanks dave browne 2e0dmb

read part 95. its right there in black & white.
the key phrase is maximum allowed range of "150 miles". thats it.

working skip there violates part 95 (however, when those regs were written,
the politicians didn't consult the science types and never knew about the
"skip" conditions that occur during increased solar activity).

Merry Christmas to you too Reg.

On inventing, it's not an imagination of the ingenuity that the rest of the world is obviously jealous about. Or you are at any rate. If American engineers and scientists didn't invent something, we improved on it. Probably responsible for more of the ideas, designs and patents that made the industrial revolution "a revolution" than all other countries combined. But of course that doesn't rub some folks well, especially if they are from countries that always know better than anything America does. Historically, these experts have made little of anything better, especially not aerials, which is a rather foolish word at that. It describes anything aloft, which for some brits may have been their imaginations more than their antennas. ;-)

"It" refers to the balun, not the antenna. The balun works on odd, but not even harmonics. Anyone have a simple explanation for explaining whether something will work on harmonics or not? For instance, how do you explain that a 40M bugcatcher won't exhibit a 15m resonance?

>The original English word for "Antenna" is "Aerial".

Hi Reggie,

The Oxford English Dictionary reveals that both terms came into
identical (RF) usage in the same year: 1902...
>But USA citizens who imagined, as is quite normal for USA citizens, they had
>invented such devices, they then had to invent another naming-word in
>support of their claims.
... and the OED goes on to reveal that no such association to USA
naming-word (curious Brit invention in that term) was made. This
archaic artifact of language (naming-word construction) has its roots
in "Cï¿½dmon's Hymn" written in the 6th Century. Such twinnings were
often found with such examples as whale's-road (meaning the sea).

When we step back to the global English perspective (there are far
more English literates and speakers in India than England), it becomes
obvious that aerials (which means "of the air") is an archaic
affectation. One may even note the curious spelling that begs another
affectation towards ï¿½rial (which would be incorrect and lead many to
the wrong pronunciation).

Old son, I enjoy such affectations, but reflect on how often you
struggle trying to understand English - take comfort in that you are
not alone. ;o)

Hi Ed,

Yup, the same as a standard Dipole.

If what you are saying about "low noise" is from charge accumulation
(snow, rain, dust....) then the DC short helps in comparison to the
standard Dipole. However this is simply remedied with a large
resistor (1 KOhm) or choke across the feed point of the standard
Dipole.

Yes, moving a current balun to a position before the tuner is a "useless" exercise but it doesn't render the balun "useless" -- it's equally effective at the input as at the output (provided that the tuner case is floated if the balun is at the input).

To answer your question about why not use one at the input and output, I recommend against using one at the input because the case of the tuner has to be floated for one at the tuner input to be effective. This has some potential safety implications. If you want to use two baluns in order to increase the common mode impedance, I suggest putting them both at the output. And for maximum effectiveness, space them about a quarter wavelength apart at the most troublesome band.

Art chose to compare his antenna to an isotropic antenna in free space
-- he reported the gain in dBi. So I compared a dipole at the same
height to an isotropic antenna in free space. This combination allows
comparison of Art's antenna in its position over ground to a dipole at
the same height above ground.

New to ham radio. Interested in building an antenna for a base station. I dont have anything yet, just in the planning stage.

Thought about buying a handheld and using that as part of my "base station" one maybe capable of 2 440 and 6. These seem cheaper used than the home units.

My question is, is there information out there on how to build one? I have a radio shack book at home that has a plan for a 440. It uses aluminum ground wire. What I find when working with this stuff is it is impossible to make it perfectlyu straight. Doesn't that effect the performance? I mean it comes coiled and when I cut it to length I cant get it perfectly straight.

Also, it is posisble to have good performance with one antenna for all the bands? Or is it absolutely necessary to have one antenna for each band? I have limited room.

I appreciate your help!

>line to feed a rotating dipole and tune it in the shack.

Should work fine, you only have to rotate a dipole 180 degrees so the loop can
be easily managed.

# 3940. Re: H.F Dish Antenna update

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-20 21:41:02 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10sehnjcbghpo6c@corp.supernews.com>
Source record: 84936

The elevation angle at which radiation is maximum (the "takeoff angle") can be influenced by narrowing the free-space elevation pattern of the antenna. A Yagi provides considerable directivity in the horizontal direction, but not very much in the vertical direction. The elevation pattern of the forward lobe of a Yagi doesn't look much different from the elevation pattern of a dipole. Therefore, the elevation patterns of a Yagi and dipole are very similar (except for very long Yagis, which do begin to have some noticeable directivity in the elevation pattern). One consequence of this similarity is that the gain of a Yagi over a dipole in free space is about the same as the gain of a Yagi over a dipole at any elevation angle when the two are mounted at the same height -- a single number is adequate to describe the gain of a Yagi over a dipole, no matter where the two are mounted (as long as they're at the same height).

There are some antennas that do compress the vertical pattern. One notable antenna in this category is the W8JK. The result is that the "takeoff angle" is lower for the W8JK than for a dipole at the same height, and the gain of a W8JK compared to a dipole is different at different elevation angles. I haven't looked at one in a long time, but believe the "Lazy H" antenna also compresses the vertical pattern somewhat, resulting in a lower "takeoff angle" than a dipole when mounted over ground.

It's not too surprising that Art's antenna has the ability to compress the vertical pattern somewhat, for the same general effect as the W8JK, due to its physical geometry. This general characteristic of a lower "takeoff angle" can be an advantage for working DX, so it might make the constructional difficulties worthwhile for some people. The reduction in F/B when maximizing gain also isn't surprising. I don't believe there's any fundamental reason for this to always happen, but it's all too often the case. Most arrays, both parasitic and driven, have relatively poor F/B when adjusted for maximum gain. It becomes up to the user to decide on the optimum tradeoff for his particular application.

An antenna or transmission line has resonances at (or near) odd harmonics. But a lumped LC circuit doesn't. A bugcatcher is a combination of the two. I'd think it likely that it has multiple resonances, but not at harmonically related frequencies.

If you want a rule of thumb, don't look for harmonically related resonances in any antenna containing a significant amount of lumped L or C, or L and C distributed over a relatively small distance.

Yes there are multiband antennas. Basically, they use some type of coil or
trap to subdivide the antenna. The full length of the antenna is used for
the lowest frequency, etc.

Sorry, that's NOT true for remote autotuners. When I was remote autotuning
my elevated-radial vertical, the autotuner was 20 feet from the antenna and
65 feet from the shack. Field strength improved the most with chokes on the
input AND output.

Yes, I hope that he meant "loop" instead of "dipole" . I still would
like to hear from others on this, too. I am re-considering my planned
installation of a loop now, in favor of the tactically easier to install
folded dipole, if I can maintain that low noise charactistic.

Hi Ed,

Aside from the charged particles introducing noise, there is no
difference. If charged particles is the noise, then I offered a
solution that reduces the issue of antennas to: no difference.

If it relates to corona discharge, then you may have to ask yourself,
what about the difference between corner fed and center fed loops
(this made a huge difference to HCJB in Quito).

Just tossing out the term "low noise" is in itself a reliance on hopes
and wishes to sort out what the noise is. This is because forcing the
discussion into more context invariably reveals the old nostrum of
magnetic antennas being immune from electrical noise. Then we get
into all sorts of equivocation which in the wash inevitably reduces
to: no difference.

You can get the same effect with a dipole by installing a toroidal
inductance (RF choke) across the feedpoint or (surprise) by using a 4:1
voltage balun. Back when I didn't know any better, I used a 4:1 voltage
balun and it was quiet but ineffective as a balun on some bands. Things
got noisier when I switched to a 1:1 choke. An RF choke solved the
problem.

Point is that a loop reduces that "noise" where a dipole allows the
"noise" to build up until it arcs across the coax connector which
causes an extreme amount of "noise". One night in AZ, my PL-239
connected to my IC-745 was arcing so loud that it woke me up. I
disconnected it and tossed it on the floor. A few minutes later,
the carpet was smoking.

Aside from the arcing waking me up and the burning of the carpet,
there was no difference.

Roy,
Thanks for the pertinent points raised in your post.
I might add that since the element centers are close to the mast
I have avoided the installation of a boom at the top of the mast
as one would do to lower the take off angle by the use of a stacked
beam. This 'top beam' provides major instability when using a single
mast. With me using my normal fishing pole elements the arrangement
will help quite a bit in mast mechanical terms. Since it is element
height over the feed element that, in the main, is creating a
compressed lobe (as I believe your post infers) I will take a different
tac with respect to the driven element, where it will be the only
element shaped in parabolic form and all others will
remain in a "V" configuration( straight portion for clamping at the
center). The parabolic shaped driver would then hopefully allow the
addition of staggered elements for other bands. The mast used will be
a 2 inch diameter fibre glass to prevent vertical radiation mutations.
Regards
Art

Ed:

You got some interesting discussion, but I wonder if any actually heard the question. Unfortunately, the question is
incomplete, and this often leads to answers to questions you never asked. What particular kind of noise do you
characterize?

Loops respond to magnetic fields, and dipoles respond to electric fields. So what, you ask? Well, if the noise you are
concerned with is locally generated RFI stuff, and you are within the near field, the shielded loop often provides
better signal to noise ratio on distant signals because of some fundamental characteristics of near electromagnetic
fields. Which Roy or Reg or a lot of others can explain a lot more lucidly than I can. Other slightly further away
noise is likely to be vertically polarized, again due to the propagation characteristics of surface waves, and any
antenna which is more sensitive to horizontal polarization and less to vertical can exhibit batter S/N on distant
signals. If, on the other hand, you are trying to receive weak local signals in the presence of strong distant noise,
well, then the reverse tends to be true. The point? No specific one answer fits all cases. If it did, there would be
only one kind of antenna.

Scott;

Thanks for the remarks about your installation. I have not given up hope for my Plus just yet. I think our problem with the receiver hitch installation is the mass of metal on the back of the vehicles. My hatchback and your tailgate. The manual does state that we should keep the antenna as far from large surfaces of metal parallel to the antenna. I am going to try using a mast to elevate the antennas above the top of the van and see what happens.

That's not at all true. Both kinds of antennas respond to both electric and magnetic fields.

An *electrically small* loop responds more strongly to a magnetic than an electric field only if the source of the field is much closer than a wavelength. Likewise, an *electrically small* dipole responds more strongly to an electric than a magnetic field only if the source of the field is much closer than a wavelength. At some distance from the source still less than a wavelength, they actually reverse -- the short dipole responds more strongly to a magnetic field than a small loop, and the small loop responds more strongly to an electric field than a short dipole.

The response of electrically large (on the order of a half wavelength and larger) dipoles and loops to electric and magnetic fields depends on the direction and distance to the source. No single rule of thumb can be used when the source is very close to anything but an electrically small antenna. The relative responses of *all* antennas to electric and magnetic fields are essentially the same as each other if the source is a fair fraction of a wavelength away (i.e., the antenna is in the far field of the source).

I have seen folks use 2 -or 4 toy slinkies (the metal kind)
what holds them up ? plastic trimmer line like on a weed-eater
The plastic trimmer line is threaded through the slinkies and stretched
across the room
, and the slinkies acted like a continouusly-loaded dipole
as short as you need it - and it can s-t-r-e-t-c-h a little too.

The tuner case was tied to a ground rod at the base of the antenna
support. In the last version, the radials were up at 20 ft. I didn't
try it without a choke on the input but adding a choke to the output
improved the ground level field strength at ~200 yards by a little
over one dB on 40m, if memory serves me right. I can't locate my
notebook at the moment. The field strength was measured using a Palomar
FS-1 and ferrite rod pickup antenna. The choke on the output appeared to
slightly reduce the received noise which is the problem I was chasing at
the time. I never could get the received noise down to an acceptable
level compared to my horizontal dipole so the vertical is gone.

What would you recommend? Building a beam for two meter? If I did that would it work ok on 440 too?

Also, I have seen beams mounted bothe on it's side and upright like an outside tv antenna. Which way is better?

# 3965. Why Match ?

Newsgroup: rec.radio.amateur.antenna

Source record: 84962

Hi All,

I was reviewing a 75 to 50 ohm resistive matching network using two resistors, the insertion lost was 5.7 db.

If we have a 100Vrms source with 50 ohm source impedance and it is driving a matched 50 ohm load then the load takes 1A and the power in the load is 50 watts.

If the load is replaced with 75 ohm, then 0.8 amps will flow and the power is 48 watts. (I*I*R) == (0.8)*(0.8)*75.

I guess I must be not be taking something in account, but 2 watts does not equal 5.7 db.

I know there must be a good reason to put the matching pad in line for the sprectrum analyizer but I don't under why.

Thanks,

de KJ4UO

## 3966. Would EMT be good for antenna?

I am new to ham radio and am trying to learn about antenna building. I have the capability to weld at home very thin material. Was wondering if EMT conduit would be good for making an antenna? It seems light weight and resists corrosion and is weldable.

I need somethign that will last. I will be putting it on top of my tv tower and I am afraid of heights. I only want to do this once.

If you only want to do it once then use some of the proven 6061 aluminum
tubing. Electrically the type of tubing will not make much differance, but
mechanically it will.

Russ,
The biggest difference in most of the screwdriver type antennas is mechanical, how it's put together, how well it will stand up under use (and price!). Electrically, most are basically the same except in power handling ability. It's been a few years since I did any investigating of screwdriver antennas so what I know about them isn't exactly current, but I seriously doubt if there have been any great 'break-throughs' in design. In general (meaning that there are always exceptions), pick one that you 'like' the looks of, can afford, and won't tip your vehicle over. All the rest is just advertising 'hype'...

I am a newbie wanting to set up a base station at my house on top of my tv tower. I am interested in building one myself. I have the capability to weld.

Do the j poles have gain to them? Are they near the performance of a several element yagi?

Can I make a dual band antenna in each of these styles?

Do the copper j poles last many years? I sometimes have high winds and lots of rain. Plus, I dont like heights and only want to do this once.

I would ideally like to reach a repeater about 70 - 80 miles away from me.

I hope you are referring to welding antenna elements, and not building a
tower by yourself

> Do the j poles have gain to them? Are they near the performance of a
> several element yagi?

Gain over what? Asking about gain without providing a reference point is
sort of useless. If memory serves me correct (and I do admit that my memory
is somewhat porous right now) a j-pole will have about the same gain as a
dipole over an isotropic radiator or 2.4dbi. A yagi would certainly have
more gain over a dipole or a j-pole. Remember that a yagi is directional,
and the j-pole is not. If you want to hit repeaters in more than one
direction, you will need a way to rotate the yagi.

>
> Can I make a dual band antenna in each of these styles?

Yes, google is your friend here.

> Do the copper j poles last many years? I sometimes have high winds and
> lots of rain. Plus, I dont like heights and only want to do this once.
>

I have one that has been up for 3 years now. The only difference between now
and when it first went up is that it is a darker color now due to
weathering. It seems to be just as strong now as t was then.

> I would ideally like to reach a repeater about 70 - 80 miles away from
> me.

That would depend mostly on how high up you can get the antenna (yagi or
j-pole) VHF/UHF is line of sight.

Hi OM,

That is the loss for using the network, and for this network it
appears to be Power lost IN the network (rather than Power not
delivered to the Load). However, this is not the best design for a
matching network, they are usually three resistors in either a PI or T
configuration.

>If we have a 100Vrms source with 50 ohm source impedance and it is driving a
>matched 50 ohm load then the load takes 1A and the power in the load is 50

No matching network is required for this scenario.

>If the load is replaced with 75 ohm, then 0.8 amps will flow and the power is
>48 watts. (I*I*R) == (0.8)*(0.8)*75.

By your description, you are still not using the matching network. If
you think you are, then the math is incorrect.

>I guess I must be not be taking something in account, but 2 watts does not
>equal 5.7 db.

Of course not. You never accounted for your two matching resistors so
you cannot assign the 5.7dB loss to them.

>I know there must be a good reason to put the matching pad in line for the
>sprectrum analyizer but I don't under why.

There are any number of reasons - accuracy and stability being
principal among them. On the other hand, the two resistor variety is
not the most suitable for accuracy (except under known loads).
Another virtue is that it will increase the input power specification
by that same 5.7dB. This very handy when you are putting a flame
thrower to its input. Burnt resistors are cheaper and easier to
replace than the input stage. One very useful 100 Ohm resistor is a
10mA glass fuse (Wollaston wire).

Hi David,

Add some radials to your vertical antenna. Research this by going to
google groups and doing a search using the keywords "ground" and
"radials."

Add a choke at the feedpoint. This can be a coil of transmission
line, or a 1:1 Current BalUn.

If you still have static noise AND it is due to charged particles
(smoke, soot, rain, snow, dust) then add a 1K Ohm resistor across the
feed point (or any handy choke of more than a 100 ï¿½H).

This is correct, if the 100 V rms source is the Thevenin emf - not the
loaded terminal voltage.

>If the load is replaced with 75 ohm, then 0.8 amps will flow and the power is
>48 watts. (I*I*R) == (0.8)*(0.8)*75.

Under those condx the load voltage is 60 V rms and the load power is
48 watts, as you indicated.

>I guess I must be not be taking something in account, but 2 watts does not
>equal 5.7 db.

Since the original load voltage was 50 volts rms and now it's 60
volts, one could argue that the load voltage is up by 1.6 dB. However,
the load power at 48 watts is in fact down by 0.17 dB

>
>I know there must be a good reason to put the matching pad in line for the
>sprectrum analyizer but I don't under why.

Interestingly enough, none of this has anything to do with your L-pad
matching network. All of your calculations above relate only to the
hypothetical situation in which you are actually "changing" the load
resistance and computing the new load power - nothing whatsoever to do
with the situation you would have when you actually insert an L-pad
between the real source and the original 50 ohm load.

A 75 to 50 ohm resistive matching pad is designed to work with a 75
ohm load and to present a 50 ohm load to the source, which it will do.
When you calculate the amount of power in the 75 ohm load before and
after inserting the L-pad you will get a significant loss, depending
upon the exact design of the two-resistor network. 5.7 dB sounds a bit
high, but it depends upon how the L-Pad losses are defined.

As to the reason for using the L-Pad, it's probably for the purpose of
minimizing the SWR on the cable between the L-Pad/Load and the source.

Since you haven't specified anything about the source, the load or what the purpose of the circuit is, one can only guess.

Hi OM,

Beams add complications for a newbie, stick with a simple vertical
until you both need and can afford these. Concentrate on the simple
maxim: Higher is Better.

>Also, I have seen beams mounted bothe on it's side and upright like an
>outside tv antenna. Which way is better?

This is the complication - both are better... depending on what you
want to do. What you want to do depends on your local Ham activity
so, as you can see, the list of constraints grows in front of you.
Simply put up a cheap antenna (one you build yourself) and let events
drive your choices from there.

In test devices the losses are not usually a problem as long as the levels are accounted for if absolute numbers are needed. The impedances must match if any tuning is done. As teh impedance of a receiver is not usaully 50 ohms over a wide frequency range , you use a 6 db pad or so to isolate the generator from the receiver . If tuned circuits are involved, the impedance missmatch (swr) can cause many problems . You tune a device for a 50 ohm source or load and then replace it with a 70 ohm device and the tuning will usually change . By using the pads, it is an attempt to keep the impedance changes at a minimum when the test instruments are removed and the device put back into normal operation.

# 3980. Choosing mobile HF antennas.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-21 17:10:21 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cq9lds$i7i$1@titan.btinternet.com>
Source record: 84877

Radiating efficiency is the most important characteristic to consider. For short mobile antennas radiation patterns are all the same, the pattern in all planes much depending on where the antenna is mounted on the vehicle, and not on any peculiaritiies of the antenna itself. A roof-mounted antenna can be very different from one mounted on the bumper bar although you may not notice much difference in practice.

The most important dimension is antenna height. All other things remaining unchanged, the higher the antenna above its base, the greater the radiating efficiency. Low antennas are quite sensitive to height.

Loading coil position is not critical. Anywhere between 1/2 and 2/3 of antenna height will provide high efficiency. Avoid heights greater than 3/4.

The physically larger the loading coil the lower the coil loss, the higher its Q and the greater the radiating efficiency. Double all coil dimensions and wire diameter, reduce the number of turns, and coil Q is doubled at the same frequency.

'Screwdriver' type antennas are best when the unused short-circuited portion of the loading coil is enclosed in a metal tube, and the used portion is at a height about 1/3rd to 2/3rds of the antenna. Again, highest efficiency occurs with the largest diameter coils with the largest wire diameter.

If one antenna looks something similar to another then radio performances will be indistinguishable from each other. So choose on the basis of which one gives the impression of being more mechanically reliable.

I am interested in sailing my hf antenna above mentioned that is in very
good conditions.
Reason: need to renew and create a new set up of antennas.
Antenna: Sommer (DJ2UT Beam)
Model: XP 707
Bands: 10, 12, 15, 17, 20, 30 and 40 meters
Balun: The balun furnished with the Sommer antennas is a low-loss
air core type using RG142 (BU) Teflon cable. The balun will handle 2.9 kW
continuous output at 30 MHz with a loss of only 0.05 dB.
This antenna it still on my tower and working very well.
For price please send one email to:
fartolopes@mail.telepac.pt

The transports costs will be at the resposability of the buyer.
If you are interestes we can sed some actual pictures, and for all the
informations concerning gain and front/back, please go to the oficial site:

http://www.sommerantennas.com/beaminfo.html

>de KJ4UO

Dear KJ4UO,

Some additional help with your L-pad -

The minimum loss L-Pad for matching 75 ohms to 50 ohms would indeed
have a loss of 5.7 dB. This is from the ITT handbook, pages 10-4
through 10-8. The design values for such an L-Pad would give the 5.7
dB loss based upon the following: Let P1 be the power delivered to a
matched load (50 ohms) from the 50 ohm source. Let P2 be the power
delivered to a 75 ohm load when fed through the 75 to 50 resistive
matching network. Then P1 / P2 will be approximately 3.715.
10 x Log(3.7) = 5.7 dB. You can work that out from the design values
for the L-Pad, which are 43 ohms in the series arm and 86.7 ohms in
the shunt arm.

> http://k9erg.tripod.com/theory.htm

Nice site. Except for the inaccurate advice warning of disastrous effects from operating a J-Pole w/o a BalUn. I use neither a BalUn nor any coiled-feedline as a choke. If my feedline is radiating, it's the most efficient feedline radiator ever made, getting loud and clear 100 mile coverage on VHF Marine between other high sites, and surface contacts between 20-30 nautical miles depending on height of vessels antenna. Another misconception about J-Poles is from at least one web-site offering plans, in which the offerer warned against grounding the antenna. Dangerous and wrong of course, as the antenna and its mast should be grounded and performs very well as such. The stub-capped tops of a copper-pipe J-Pole antenna at the highest point of a structure will indeed be an air terminal for lightning that was going to strike that immediate area anyway. Maybe my lightning down conductors heading 180 degrees from the J-Pole to series of ground rods are the SECRET <G>.
--
Users considering a static and lightning-grounded (and un-choked) J-Pole should make sure the British did not already invent/patent this form of improvement to the J-Pole radiation pattern. ;-)

I'm not into a lot of VHF/UHF work personally however my OM likes loop antennas. However loops don't have any significant gain unless you stack them. Many people do like beams and some build their own. There are MANY good antenna books available from the ARRL. Start with The ARRL Antenna Book. As for working on more than one band, only those designed with that in mind will work adequately on two bands. If it is designed for only one band, it will be very bad on the other.

> Also, I have seen beams mounted bothe on it's side and upright like an
> outside tv antenna. Which way is better?
>

Vertical elements on beams will yield vertical polarization and are thus suitable for repeater work and a lot of FM simplex.

Horizontal elements will yield horizontal polarization and are thus suitable for weak signal work such as working distant SSB stations (horizontal is the custom on SSB).

You really need to get and read a good antenna book. A newsgroup cannot give you enough detail.

EMT will corrode very quickly out in the weather - particularly if it's welded, aluminum will not. EMT is much heavier per foot than aluminum, etc. Aluminum antennas are easily constructed by using hardware store U-bolts and other standard fasteners, usually stainless steel and they work fine. Yes aluminum is more expensive than EMT but it's worth it for a number of reasons. I suggest you follow the examples of those who have been building antennas from aluminum for decades.

It appears that you forgot to put the resistive matching network
into the circuit. There must be a series resistor in there between
the source impedance and the load impedance to obtain that 5.7 dB
of isolation.

No, the tv tower is already up. I meant I can weld the elements. (Of course only if it is weldable material.) I was wondering if emt tubing would be a good choice?

The antenna would be about 25 feet up. I had someone else tell me that a j pole does not work very well. Is this true?

I can rotate the mast by turning the antenna rotor hooked to my tv down stairs. The only pain would be running down stairs every time I want to do it.

What would you do in this situation? Can you get as good as or better performance building one yourself?

Aluminum would be a better choice than emt tubing. The EMT stuff will rust
after a while, and is not as strong as it appears to be. It would also be
heaver than aluminum tubing for making a yagi.

You might not need to weld the tubing anyway. You can get nesting tubing,
and connect lengths by splitting the ends a bit and using hose clamps. Also
for the bands you mentioned, the tubing would more likely need to be cut to
length, rather than joined together to increase the length.

>
> The antenna would be about 25 feet up. I had someone else tell me that

J-poles work well, but it all depends on your definiation of "working well".
The higher the better, 25 feet would probably work, but it depends on the
terrain between the repeaters and your antenna.

> I can rotate the mast by turning the antenna rotor hooked to my tv down
> stairs. The only pain would be running down stairs every time I want to

If you already have ther rotor that would be ok, just leave a reasonable
distance between the tv antenna (if there is still one there) and your yagi.

> What would you do in this situation? Can you get as good as or better
> performance building one yourself?
>

I think that I would put up at least 2 antennas. A j-pole first, and then a
yagi. If I had a multimode rig, I would put the yagi in a horizontal plane
for ssb use.

As for performance, you can make just about anything that the commercial
manufacturers can. It might cost more or less depending on your skills and
what you have available for materials.

Hardware mega mart -- home depot, lowes, ace, or your local hardware store.

Just about anything you might want for building antennas can be found in the electrical, plumbing or assorted hardware aisles.

Several manufacturers of precision matching pads might disagree!
Two resistors is enough, although you have to remember to add a rather
odd number (unless the measuring equipment can add it for you). If you
add a third resistor, you can make the correction a straight 6dB. That's
probably the only virtue.

Hi OM,

The consensus is that it is not. If you are going to invest your time
and effort, short-cuts generally lead to repetition. You wanted to do
this once? You are in the wrong hobby. Better is how to plan doing
it many times, but planning to do it in the least stressful way.

>The antenna would be about 25 feet up.

You had a range requirement of upwards to 70 miles. With a 25 foot
elevation, your mileage range is roughly the square root of twice that
- or 7 miles. You can double that if the other antenna is up equally
far. If you are on a rise of land above the mean level, add that to
your elevation. If the antenna at the other end is much higher,
compute its range (hopefully a mountain top).

>I had someone else tell me that
>a j pole does not work very well. Is this true?

Varies by user as it is susceptible to transmission line length
problems. These problems are SWR related. However, that aside, as a
principle antenna for the range you ask, then that antenna at the
other end has to make up for a lot (it better be higher, an array, or
some combination).
>
>I can rotate the mast by turning the antenna rotor hooked to my tv down
>stairs. The only pain would be running down stairs every time I want to

You have to now investigate if your tower/rotator can in fact stand
the additional wind load factor (or weight, or moment).

>What would you do in this situation? Can you get as good as or better
>performance building one yourself?

Depends on your resources. It already sounds like you are shy there
in finding aluminum of the proper grade. Best advice is to visit a
metal scrap yard in the crummy part of town. Or - bite the bullet and
pull out your wallet.

If all this is to hit a repeater, and a popular one, you should simply
try it and see what happens with a rubber duck. Then build a simple

ground plane ($5) and hoist it as high as you can (on a broomstick out the 2nd floor window will do as a test). Popular repeaters are popular because they solved all these problems for you (by being high and having gain).

The problem is that without the balun, the feedline is part of the antenna. So anyone trying to get the same results as you do has to use the same length of feedline, position it the same, and maybe even ground his rig the same way you do. (That is, have the same path from the rig to the Earth through the power wiring.) If he does it differently and happens to not be as lucky as you, he could take a bit of a beating in field strength. And both of you could be running the risk of causing RFI if you're running significant power and your feedline runs close to house or telephone wiring.

If a balun is used (actually, two are likely necessary, spaced about a quarter wavelength apart), only the J-Pole will radiate, and the user won't have to worry about lucking out and having just the right feedline and orientation.

I think the reason some people love J-Poles and some hate them is that some, like you, have been lucky with feedline length and placement and some haven't. I prefer to depend on design rather than luck to make my antennas work, but lots of folks are perfectly happy to just roll the dice.

Dear KJ4UO,

I have fundamental objections to responding to respondants, so I will continue to address this thread directly. It has been suggested that a virtue of the T pad would give a clean 6 dB loss instead of some "not-so-nice" loss, like 5.7 dB. Well, that's not a problem because the L-Pad can also be designed for exactly 6 dB. In fact, it can be designed to provide ANY loss you want, so long as it's AT LEAST 5.7 dB. You see, the 5.7 dB L-Pad happens to be the MINIMUM loss design for that particular mismatch.

It is a repeater 80 miles away I would like to hit. I would also to try
long range simplex if possible.

The other problem is the transmision line will have to be long,
probably35 feet or more. Is this a problem?

Dear KJ4UO,

First, I must apologize for not noticing that your posting DOES
mention that the application is a Spectrum Analyzer. That being the
case, I can be much more enlightening about WHY we want a flat line
(no standing waves).

A spectrum analyzer is of use primarily in showing WHAT frequencies
are present in the specturm AND what their relative levels are. Unless
the line is flat, the relative levels will be distorted or inaccurate.
This comes about due to the fact that a mismatched line becomes an
impedance transformer that is very frequency dependant. That is, some
frequencies will be artificially enhanced and others artificially
subdued due to the varying impedance impedance seen by the source.
Conversely, when the source sees a perfect match across its acceptance
spectrum, only the built-in non-linearities will degrade the accuracy.

In short, the line must be properly matched in order that the spectrum
analyzer give the accuracy that it is capable of.

BTW, it should be understood that the matching L-Pad, in order to be
effective, must be physically located at the Spectrum Analyzer end of

the line - not at the source end of the line.

Interestingly enough, hams do not usually take this into account when tuning an antenna system, because they are only interested in a flat line for that short little piece of coax between the tuner and the transmitter. They don't normally do anything about the horrible SWR that exists on the feedline - Hi!

>for that particular mismatch.

Hi Bob,

The difference between 5.7 and 6dB is immaterial if neither is calibrated. As for the desire for a nominal 6dB pad, that too is hardly of great merit for quality measurements with a good Spectrum Analyzer.

Just like directional coupler design, precision applications focus on directivity and sacrifice round numbers in coupling to achieve better separation of ports. A 6dB attenuator will isolate your precision gear from the unknown better than a 3dB attenuator, but not as well as a 10 or 20dB attenuator.

Now, as to the term isolation. It has a variety of meanings which in this case means that your measurement is less perturbed by the literal unknowns of your proverbial unknown being measured. That is, in your attempt to find a value (the proverbial unknown) your accuracy can be upset by variables whose magnitude can affect that accurate determination. Large attenuators obviously de-sense the instrumentation, but if you have sufficient dynamic range, then that is not a debit, but actually an asset. Hence de-sense or isolation is benign. When this large attenuator is placed on the source, it reduces the load's influence to pull or mismatch there too.

This says nothing of actual mismatches, it simply presents what is called swamping. That is, you introduced known and controlled losses to buffer the measurement. Later you can subtract out the losses to find your proverbial unknown.

I already alluded to the virtue of using attenuators to increase the power tolerance to the input of a Spectrum Analyzer, aside from this, the only practical use of attenuators is to introduce controlled loss to isolate the unknowns' influence.

To answer "Why Match?" returns us to isolation. Once this is achieved, the measurement can be trusted to be faithful in proportion

to that isolation. With this example of a simple 50 to 75 Ohm conversion, that measurement's faithful accuracy is fairly good. As for it being a ~6dB attenuator, by placing it into another test with an unknown, it will offer mixed results - a T or PI configuration at a higher attenuation would be far more flexible, and faithful.

>It is a repeater 80 miles away I would like to hit. I would also to try
>long range simplex if possible.

Hi OM,

I've touched on the requirements for you and the repeater. You will
be successful in direct, root proportion to heights for simplex.

The difference between a J-Pole or Ground Plane, or vertical Dipole,
or Discone, or sleeve Dipole.... and so on, will be marginal. The
difference between a simple vertical (as were all those in that list)
and an vertical array has gain for the same power. However, the
difference between that same array compared to any antenna turned 90ï¿½
to it can have -20 to -30dB (those are minuses) difference IF you
choose the wrong orientation WRT the listener. This is called crossed
polarization and can be a killer (you wanted to put this up once, and
if that once happens to be cross polarized to the majority of the
traffic you want to engage in - kiss them good bye).

You should be advised that FM is usually vertical, and SSB is usually
horizontal. See any problems with trying to make one antenna work
everywhere?

>The other problem is the transmision line will have to be long,
>probably35 feet or more. Is this a problem?

Of course. You simply have to investigate by what degree. RG-174
would be like plugging your ears and mouth, other bigger and more
expensive lines would not. Fortunately this is very simple to resolve
as line is characterized in the loss per hundred feet (if you only use
35 feet, you need only reckon 35% of that quoted loss).

For a j-pole, you might look at the Arrow Antennas site -- for one you could purchase, or, if you're really handy with metal, you could replicate one of their designs -- the diagrams & dimensions are all there.

You might try a non-ferrous scrap yard in your area .....I have seen really nice stuff of there for little more than scrap prices. I used to be able to walk about the yard and look about but the insurance industry and the lawyers put an end to that in most cases. A lot of the large scrap yards have been gobbled up by the big national and international conglomerates. I remember seeing piles of Al tubing rounds, squares, angles et al. Try hanging out at the local tavern near the yard ...it is amazing what a few beers will get you ..... this is in all seriousness .....

Take care ...Merry Christmas all ..... Tom Popovic KI3R Belle Vernon Pa.

I have ordered some from Texas Towers.

http://www.texastowers.com/

I think it is the .058 sizes that telescope into the next size up. Also I
think that for UPS shipping you will have to get it in the 6 foot lengths.

For two meters and 440 I would suggest a J-pole. If you look on the arrow antenna site http://www.arrowantennas.com/j-pole.html
He gives you the information to build your own. FM by mutual agreement is vertical where sideband is horizontal. This relationship is used on VHF and UHF.

On 6 meters a simple dipole will get you started. Use the formula 468/desired frequency in MHz equals the total wire length in feet. Make it a little longer for adjustment purposes then cut it in half. Add a center insulator and end insulators. At low power (<=100 watts) use pieces of PVC pipe. Tie the shield of the coax to one side of center and the center conductor to the other.

Welcome to amateur radio and if I can help you in any way just e-mail me.

>>me.

How many miles away don't mean much.

I have no problem reaching a repeater 100 miles away with only
5 watts & a Open Stub J-Pole. BUT, this is a big BUT.
My location in Cheyenne WY is 1000 feet higher than Denver,
and the repeater is on a mountain top 3000 feet above Denver.
That is true line of sight if you could see that far.

Now if you live in the flat lands of NE with antennas only 30 to 50 feet
high. You would be lucky to get 40 miles with 50 watts.
If you live in a valley in the mountains you may only get 4 or 5 miles.

It all comes down to Location, Location, Location.

Hi Roy, thanks for the comments. It certainly may be luck as you say, but if so it is exceptional luck ;-) 25 watt marine transceivers rarely perform as well as mine does in this setup. So well that it is highly unlikely that the sixty odd feet of 9913 feedline radiates much if at all. The original configuration had the horizontal (with later vertical drops to ground rods) lightning down conductors added last year, replacing a simple static ground. Coaxial lightning surge arrestor was also added, with shield-grounding. None of these alterations made any noticeable change in the antenna's long range receive and transmit performance. There never was any connection between the transceiver and AC power, using instead a 12vdc deep cell battery with a 12v

charger floating the battery.

Jack Painter

# 4014. Antennas vs Antennae

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-22 00:15:53 UTC
From: Jim <IHateSpam@NoSpam.net>
Message-ID: <R03yd.1312$v_.1114@fe61.usenetserver.com>
Source record: 84911

From Kraus' 'Antennas', first edition, footnote on page 1:

In its zoological sense, and antenna is the feeler, or organ of touch, of an insect. According to usage in the United States the plural of "insect antenna" is "antennae," but the plural of "radio antenna" is "antennas". However, the usage in England makes no distinction, the plural of both "insect" antenna" and "radio antenna" being "antennae."

**********

So for those not native to the USA or England, it depends on where your English teaher came from, I guess.

The point I was trying to make was, if the L-pad was 'not the best
design for a matching network', why are there so many about?
It gives the minimum loss for a match in both directions (with the 43and
86 ohm resistors). What works better?
Ian.

It will also depend - a lot - on what you have available in tooling. That's why J-poles and quagis are favorite do-it-yourself 2M antennas - you can easily make either, and well, with typical home hand tools.

I've used EMT several times successfully - mostly for 10-meter work. I
didn't weld on them - just cut and drilled.
I expect welding would destroy the galvanizing and cause corrosion - unless
you plan to re-coat those areas with zinc.
One vertical dipole I made used a pvc junction box between the 2 EMT pieces.
I fed the coax thru one of the EMT ends thru to the junction box, where I
connected the coax to the conduit using stakon terminals and sheet-metal
screws.
The dipole was suspended from a tall tree branch. - and worked great for
years.

## 4020. tnx/tvi??Transmitting from hotel bedrooms.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-22 02:27:32 UTC
From: ml <m@dti.net>
Message-ID: <m-CCB9F8.21273321122004@news.verizon.net>
Source record: 84917

thanks for all the cool tips , seems like i am trying to work in a less
than ideal condition perhaps a dipole or random wire might be all i
can do regardless of how poor it might be ie if the hotel is metal ...

but surprized nobody touched the TVI issue , so of the few
suggestions made here, any idea which is , isn't the best for
avoiding tvi and any tips on how i can minimize tvi , in general w/a
for ex center fed coax dipole (i'll be using a mac200)tuner

thanks again all

The aluminum available at these stores off the shelf is not T6061. For the new comers, Aluminum is specified by what other metals are mixed in with it making it an alloy. T6061 alloy is what is used for anything that has to be both strong and light, like antennas, airplanes, etc. The stuff sold in the hardware megastores is too soft for anything except relatively small antennas. I had some aluminum tubing nested together to about 18 ft tall, and it got bent in a strong wind and eventually broke.

One other point, EMT is soft so don't think that just because it is made of steel that it won't get bent. I also think it is more brittle than aluminum (if someone wants to dispute this, go ahead---its just my conjecture) and will be more likely to break in gusty winds.

>Ian.

Hi Ian,

The topic is Why Match? and the context is with bench gear,
specifically a Spectrum Analyzer. It is pleasing that no sardonic
quips as to this device's suitability for antenna matching has sallied
forth. Attenuators serve a limited purpose - Isolation. They serve
this well when they don't introduce uncontrolled error. They also
serve as range extenders as do directional couplers, often with
attenuators paired with them.

In the case of using them with couplers, they insure port isolation by
insuring port loading. They buffer any deviance from an expected 50
Ohm load that may be presented by monitoring gear attached through
them to that port. This is by and large the context of the mini
circuits links you offered. The extent of this "insurance" can be
observed by computing how much load is presented to the affected
instrument when the attenuator is left open, or shorted. T or PI
configurations show a higher tolerance. An L Pad is a special case
(less general form) of either T or PI, being that one of the three
elements is replaced with either a short or an open.

If you go to the ARRL web page, you can find a very good antenna book. It
well worth the price. One of the fun aspects of being a ham is experimenting
with and building antennas (or is it antennae) . To enhance your fun with
expermenting one of your first purchases (after a radio) might be an antenna
analyzer like the MFJ 259 . You'll find yourself experimenting with matching
sections and different transmision lines as well. You can be an antenna nerd
in no time!

Hi Ian,

In following up the links that you provided, there is a superior
reference found at the same site:
http://www.minicircuits.com/appnote/an70001.pdf
which in turn leads to a treasure trove on the topic that supports my
favorite discussion on Mismatch Uncertainty. By following the links,
they offer you articles and software to compute the accumulation of
errors (and loss) found in mismatched sources looking at mismatched
loads.

A notable quote:
"A fixed attenuator can help to lower the VSWR of cascaded
(connected) components by providing isolation between the
impedances, effectively masking the impedance mismatches."

For both mismatched source and load, one handy shortcut offered is
that the system suffers a SWR that is not the aggregation of the two,
but the multiple of the two. This is not particularly significant for
a source SWR of 2 seeing a load SWR of 2 (same result of 4 for either
addition or multiplication), but above this value and loss begins to
climb dramatically.

But remember that was the *first* edition of Kraus, reflecting the usage of a half-century ago.

At that time, the word over here was "aerial"; and also "wireless" rather than "radio". "Antenna" was a new Americanism, and we hadn't really decided what to do with it.

Individual preferences ruled quite strongly - and were very much influenced by the preferences of one's former Latin master. I recall a college friend who was determined to speak of "owdio" and "widayo", because that's how he'd been taught to pronounce those words. "Antennae" was just another of those Latinate plurals, but was never in wide use by British engineers.

Today, we generally use the American terms for engineering (including amateur radio) and save the Ancient British language for older people and arts graduates.

# 4027. Body Worn Antenna UHF Range

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-22 11:53:39 UTC
From: pedroclaro@gmail.com
Message-ID: <1c732ffa.0412220353.5512a61f@posting.google.com>
Source record: 84824

Greetings,

I'm currently developing a project which requires a specialized antenna. The system consists in a sensor equipped suit that delivers the data to a server. I'm having problems findind a suitable antenna for the suit, since it requires to be integrated on the suit or in a backpack (whip antennas are out of the question, since the suit can't have any holes). The main problem is the human body effect and the size constraints. Gain is also a major requirement since the range of the operations will be 400 meters with line of sight.
(Server side: 10 dBm Tx Power and a 6 dB whip antenna, Suit side: -96 dBm sensibility- freq:433 MHz)

I've tried a patch antenna (similar to the one provided by linx technologies) but it didn't perform well. I've also tried a small whip antenna but the ground plane dimensions aren't suitable for integrating this type of antennas in the backpack. I've also found a dipole body worn antenna ( http://www.panorama.co.uk )., but I'm not sure of its performance. Currently I'm trying to develop my own antenna, which consists of a pcb small loop antenna. I'm asking for sugestions and maybe antenna references for this type of application.

Thanks in advance.

Hi

was wondering if their was anything that could be done (antenna/feedline wise) to reduce chances of giving off interference from any type of wire antennas

such as for ex a center fed coax fed dipole i'll use a 1:1balun at the end, try to make dipole resonant

i believe the coax run should also be within 1/2wave or so

(everying at radio end is ok , good grounds ,tuner etc)

any tips??

Depends on what you mean by "giving off interference". In my experience, most interference situations today involving HF are the result of a perfectly clean fundamental HF signal being detected by an appliance or other electronic device which should be rejecting such signals. There's nothing you can do to your HF station to minimize that other than to increase the separation between the HF antenna and the device experiencing the interference (or reduce the transmitted power). Depending upon the device in question, use of bypass caps on the AC line and/or ferrite chokes on the line cord and other external leads MAY provide relief. It's certainly possible that feedline radiation is contributing to the problem and in that case judicious use of a balun and proper grounding may provide some relief.

I like the looks of that. I wonder if I could use stainless? Is it
necessary to use a balun on that?

At the same height, what would the difference be between this one and a
6 element yagi?

What are those red things on the top? They look like wire twisters.

22/freq (in Mhz)

See: http://www.hamuniverse.com/jpole.html

Roy has pointed out that a Balun is a good idea. The above site recommends at least 4 coils of feedline at the feedpoint as an RF choke. I used neither and had phenomenal "luck" with a 60' feedline and later added full lightning protection with no detectable change in the prop.

>but surprized nobody touched the TVI issue , so of the few
>suggestions made here, any idea which is , isn't the best for
>avoiding tvi and any tips on how i can minimize tvi

Hi, I would think the reason no one touched on the TVI issue, is that it is almost unavoidable. TVI is caused by RF getting in the TV antenna terminals and causing overload of the TV front end, or rf getting into the AC power cable feeding the TV.
What you are attempting is to produce enough RF energy for communications, but not enough to cause TVI. The first thing I would try is reduce transmitter power to a point where the TVI is not there. Communications probably won't be there either. Low power CW would be the best mode. Least TVI, best chance of being heard.
Get the antenna as far away from the TV and building wiring as possible. Outside the building would be best. Make sure only the antenna radiates, not the transmission line. Use a choke balun on the transmission line. Some TVI filters on the TV might help, but if your antenna is inside the building you will probably get into the TV distribution system. This will insure that you are messing up every TV in the Hotel.
Every time I have tried to operate with the antenna inside the room, I have experienced TVI. Usually it's not that bad even at 100 watts, but it is still there even with 10 watts. My solution was not to worry about TVI cause I did not transmit that much. With the antenna in the room, performance was so poor I couldn't hear anyone to talk to.

Hi OM,

I don't see what holes have to do with your problem unless the suit is not of fabric but made of laminar plastic, say (very uncomfortable if so).

>The main problem is the human body effect and the
>size constraints. Gain is also a major requirement since the range of
>the operations will be 400 meters with line of sight.
>(Server side: 10 dBm Tx Power and a 6 dB whip antenna, Suit side: -96
>dBm sensibility- freq:433 MHz)

Size is not much of a constraint (for a dipole size of 34 cM). 400 meters is not that far for 10dBm (neglecting the "6 dB whip antenna"). Sensitivity suggests you can tolerate 106 dB path loss which would not be found in 400 meters distance (about 80dB path loss, less with "6 dB whip antenna"). This leaves something like 20 to 30dB headroom before you consider body proximity and its attendant loss.

> I've also found a
>dipole body worn antenna ( http://www.panorama.co.uk )., but I'm not
>sure of its performance.

It is simple enough to build and test certainly. There is absolutely nothing remarkable about it, and the molded plastic T contains only wire connections of the two conductors (coax) coming to it. Given your constraints, you don't have much choice in how it performs. If it doesn't work, you will have to move either the suit closer to your server, or the server closer to the suit (or increase power/sensitivity).

>Currently I'm trying to develop my own
>antenna, which consists of a pcb small loop antenna. I'm asking for
>sugestions and maybe antenna references for this type of application.

A small loop is not going to give you gain and putting it on a PCB is not a solution with any advantage. Such claims to the contrary (should you encounter them in the marketplace) are merely advertising hyperbole with no particular merit. The dipole your link leads to is the common reference against which all antennas are compared to and any loss suffered by its proximity to the body will be suffered by all others equally from the identical problem.

If this loss is intolerable, you must put some distance between it and the body, but aside from your "pack," you have painted such solutions out of the picture through your constraints.

As an aside. Your biggest problem will be with multi-path reception. The problem here is multiple reflections between and around the two antennas that will cancel the signal through any movement of your suit across a quarter wavelength (17 cM or so). This could be a mild problem, or it could be severe, or it could go unnoticed. This is all a function of reflective surfaces within that same range. The solution is multiple antennas performing in what is called "space diversity." Research this term as a key phrase in combination with the key word antenna. The rules are very simple and still within your implementation.

The little red things on top are just plastic caps.

Element spacing & element size are critical.
Check the "Parts Catalog" & the "Instructions"
for element spacing. It's all there, even a photo of the bracket.

If you change the diameter of the elements, you will need to start
over with the spacing to tune the antenna.

As for Stainless Steel, don't bother, been there, done that.
Tried making some out of Stainless Steel CB Whips.
A very noticeable difference in performance.

You really want to build your own ?
Buy one from Arrow Antenna, copy it,
then send it back for a refund. Only cost you for shipping.
Got to warn you though, I have not got one back yet.

Why would stainless steel provide different performance? Can you use
regular mild steel for the angle iron bracket? Maybe paint it so it
would not rust?

If you do change the element size, how do you determine the proper
spacing?

I appreciate your help! I like the design of the antenna and its
simplicity.

I have been asked on quite a few occasions how to dump my programs to a printer. There appears not to be a simple way.

I have just uploaded to my website a procedure which at least works. It involves actually going via my website and using the "Paint" program which usually comes with Microsoft Windows. There may be other programs which will do the same thing. I am indebted to Jack, G3PVG for the basic procedure.

Interested? Go to "Dump Program Results to Printer" in the "Index" section on my website.

May I suggest the Carolina Cyclone antenna? I am the builder of this product and I can save you a bit of money.
I build them of .065 wall aluminum, the coils are of black nylon and the wire is #14 tinned copper wound at 8 turns per inch. They are solid performers and come in 2" and 3" diameters. Most screwdrivers are basically the same, but one should avoid those that use PVC coil forms and flimsy contact stock. Mine have no PVC and all parts are machined for precise fit and finish. Before you purchase, won't you visit www.qsl.net/k4kwh . I can save you money on your purchase and give you pleasing asthetics and perfomance as well. The Carolina Cyclone has been shipped all over the USA and are serving well (www.eham.net) .

Best Wishes and Happy Holidays,

Jerry

Let me suggest that you order a copy of the ARRL Amateur Radio Handbook. Just like any other hobby, this one has a bible that answers most of the questions that come to mind. You can save yourself the delay of having to ask and wait for a reply.

To answer your questions.
A J-pole requires a balun to eliminate feed line radiation.

The difference between it and a yagi at the same height can be likened to a yard sprinkler vs. a hose nozzle. Same amount of water comes out the hose, the j-pole sprays the signal all around, the yagi is the hose nozzle. Are you trying to get a crowd wet, or a single person?

On VHF your more often limited by line of sight distance than signal strength. If your beyond line of sight, a gazillion watts or a 100 element beam won't help.

The red things keep you from poking your eyes out.

Look for Mr Snappy 95. It was made for Windows 95 but it works in XP to take a screen shot. I have used it to send someone a screen shot to show them their PSK signal. One source is http://www.nascanada.com/Software.htm Their description of it says: This is an older screen capture utility. But its very small and powerful and we have discovered that it works with Windows 95, 98, ME, NT, and 2000. It will probably work with XP as well. It can capture the whole screen, the active window, or a selectable area of the screen. It can put the captured image to a file, to the clip board, or you can print it out directly. This is a must have utility.

Hi Doc, You have 4 quadrants of 90 degrees, and a bi directional 180 degree antenna. You would have to rotate the antenna 180 degrees to get 360 degree coverage of the main lobes. If you only rotate 90 then there will be 90 degrees somewhere that will not get the benefit of the main lobe. Am I wrong?

I would agree. And even if you're successful in your own hotel room at reducing TVI, that doesn't mean other rooms (a few feet away whether up, down or sideways) won't be picking you up. So when I operate out of a hotel room, I don't worry about TVI. Heck I'm not watching my TV when I operate anyway... ;)

BTW I use the same philosophy at my home station (with a stealth antenna). My neighbors have never complained of any TVI and I think the biggest reason is that they don't know I'm a ham.

Selfish? Perhaps. But as was pointed out previously, *my* signal is clean...

> Every time I have tried to operate with the antenna inside the room, I have
>experienced TVI. Usually it's not that bad even at 100 watts,

I think that 100 watts is a bit excessive inside a hotel room, but not so much for TVI as for radiation exposure to yourself and nearby neighbors. But I seldom had to use an inside the room antenna. I was almost always successful at sneaking a wire outside or clamping a hamstick out the window or to the balcony railing. I seldom run over 25 watts and since I always use CW that is usually sufficient for good solid QSOs.

>With the antenna in the room, performance was so poor
>I couldn't hear anyone to talk to.

That is usually always my biggest problem with hotel operating. Even with the outside antennas the QRN seems to always be exceptionally high. Probably all those electronic devices getting revenge. But still, I have much fun with this type of operation.

Current rig: TS50, small switching 10A power supply, 100' or so of no.22 wire, MFJ travel tuner, MFJ mini keyer, and all fits in a small computer suitcase. (The Hamstick is stolen off the car if necessary.)

Ian, I just KNEW some bleeding thing would cock it up.

My system is Windows-98.

And, curses, my brand new standby lap-top has Windows-XP which I didn't try it out on.

Very likely future versions of Windows won't be interested in DOS at all.

But I still think there MUST be a way of doing it even with Win-XP. Yes, we have a lot to thank Bill Gates for!

Computer software is still stuck at the stage where "Puffing Billy" was in the early Victorian age of steam.

Has anyone tried a prigram called Printscreen to do that ?

I have not used it in several years but at work on windows NT we used it to
dump a dos program data screen to the printer.

It seems to work for me if I use the dashed block in the toolbar to
highlight the text I want and copy it to the clipboard, then open up the
Wordpad program and paste it to that program. From there you can do what
you want with it. This is using windows 98.

Here is an interesting example of wearable antenna. It is directional,
alas...

http://www.wearable.ethz.ch/bluetexantenna.0.html

Here's how to modify this concept to make it "quasi-omnidirectional":

Make a dipole feed on the apex of the shoulder, drop one radiator down the
shoulder in front of, another - behind the body. Stitch it inside the suit.
For radiator, use one inch strips of material similar to one on the website
above, or any sort of fine conductive mesh. Match by adjusting lengths of
the radiators not to expected resonant length but to low SWR at your
required frequency. If the impedance will be too low - offset the feed
point.

Good luck.

Andrey

PS: say hi to Mr. Fractenna - he is playing his usual stunt, funny to watch.

About two eons ago I got tired of trying to "communicate" the outputs I get from my assorted technoid's programs which my e-mail recipients don't have installed on their hard drives. One cannot ship a CAD file, or a Mathcad file or an antenna modeling file to somebody who does not have the corresponding software up and running. Very frustrating.

After much thrashing I discovered the solution: Screengrabs via Gadwin. It's freeware which generates .png files which can be opened, viewed and printed in any Winbox running any O/S from 98 forward including XP in all it's sick forms. Gadwin can grab anything and everything you can bring up on your screen and it can be not only viewed, it can also be printed and stored for future use.

http://www.gadwin.com/printscreen/

Double-click on any .png file and it'll come up on your browser. Including Firefox.

As soon as I log off here Reg I'll run one of your gems and e-mail the output screen to you as a demo.

Clipboard?

Sort of but the screengrab programs take the concept much farther than just Alt-PrintScr which only creates ponderous Windoze .bmps. In the case of Gadwin it will produce not only .bmps, it can also churn out .jpgs, gifs, tifs and others. The .pngs it creates are amazingly small vs. the rest which matters when tossing image files around by e-mail. The size & area of the capture window can be mouse-defined anywhere on the screen and the view size of the output image can be controlled via adjustable magnification. Gadwin is a nice little piece of freeware but the payware screen grab programs like Snagit take the fine art to much higher levels.

In any event I've found that Gadwin is far more useful than the Clipboard routine when it comes to doing chores like capturing, storing, printing and e-mailing screen grabs.

There are several screen grab programs out there that will do the job.
My favorite is WinGrab. Its main features are:

* Freeware: No registration and no nags. You are free to use the
program at home and at your office (i.e. commercial use).
* Hot keys: Trigger capture by pressing user-defined hot keys. One
key for hiding/showing the program, one key for capturing a window and
one key for capturing the screen.
* Auto-save: Triggered by a hot key, the program can capture +
save to file in one operation, without any user intervention
(automatic incremental file naming).
* Time-scheduled capture:New Capture + save to file (auto-save) at
regular time intervals.
* Cursor capture: New The mouse cursor is included in the
captures.
* Index images: Can create index images (overview image with an
array of small images). The tiling of images can be freely set by
user. Useful to get an overview of images.
* Color reduction: High quality color reduction to 256 colors (8
bits/pixel). Useful for reducing file size.
* Cropping: Crop images after drawing a bounding rectangle with
the mouse.

* Clipboard: Copy and paste images using the Windows clipboard.
Useful for exchange with other programs.
* Graphic formats: Supported formats are jpeg, png, tiff, bmp. The
degree of jpeg compression can be set by user, giving full control
over image quality and file size. Can create progressive jpeg's and
interlaced png's.
* Batch printing: Print a list of images with any number of images
tiled on the same sheet of paper (similar appearance as index images).
Useful for printing a series of captures.
* Image-viewing: Useful as a simple image-viewer. To open an
image, doubleclick on the file or drag & drop it on the program
window. Jpeg images can be decompressed to a smaller size for faster
viewing. Fast zoom in/out by clicking the mouse buttons.
* Image text: Can store text in image files (jpeg, tiff, png).
Useful for storing notes about images.

It can be downloaded at: http://www.andras.net/wg.html

Why would stainless steel provide different performance? Can you use
regular mild steel for the angle iron bracket? Maybe paint it so it
would not rust?

If you do change the element size, how do you determine the proper
spacing?

I appreciate your help! I like the design of the antenna and its
simplicity.

At one time I had a chance to acquire a large number of Stainless Steel CB
whips, cheaper than the cost of aluminum.
I used 8 of them to make a 4 element Yagi just like our regular 146-4S.
It works, SWR is low, but it just does not work as well as the aluminum
elements.
Used a couple to make an OSJ, because of the smaller diameter, the spacing is
closer to get it to match But like I said there was a very noticeable drop in
performance. I really wanted it to work, would have been a good market for
them for mounting on 18 wheelers.
(Don't ask, I won't sell ether of them.)

As for making the bracket out of steel, Why ? it's harder to drill, harder to
tap. The 3/16" stress aluminum angle is a lot stronger than it needs to be.

As for determining the proper spacing, if you know the exact impedance
of the 1/2 wave, there is a formula for figuring the diameter & spacing.
Easier to just adjust the spacing for lowest SWR.

Unlike other types of J-Poles the OSJ does Not need a balun or choke.
It was designed for direct connect to coax.

Nope. It doesn't work for me.
When running a DOS program, it does a capture, but I only get a black
screen. Same as Gadwin.

Both work OK in Windows XP, but really no better than using 'Print
Screen' to capture the screen image to the clipboard.

For me, it's either run the DOS prog in a Windows window (screen dump
works), or run full screen, and use Print Screen to capture the text,
and paste it to a blank Word document (then tidy it up a bit).

I can live with this.

# 4074. Using a Loop Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-23 23:48:43 UTC
From: onyx49@juno.com
Message-ID: <1103845723.740688.290100@z14g2000cwz.googlegroups.com>
Source record: 84871

We know that a loop antenna is good for mag fields and a diploe
is good for E fields. But since the E field is (120 pie) times
stronger than the mag field, why is there any consdieration to
using a loop antenna?
This question has gnawed at me since my EE course work, but
nobody seems to have a situation where the mag field is better
to receive.

TIA,
Dave

Not if you have more than one bastard! -us ending = singular.

"Non" refers to the verb and must be next to it, otherwise you have a
Latin equivalent of a split infinitive and we must always try to never
split infinitives. According to scholars the version you cited
(which admittedly is more often seen) came about when posters were
published years ago for comsumption by engineers and written by
engineers who should have stuck to Pig Latin...in which case it would
be:

Ontday etlay hetay astardsbay rindgay ouyay ownday. :-)

W3JT Who is pentalingual, but as you might guess none of the five is
Latin.

Source record: 84774

First, a loop isn't "good for mag fields" any more than a dipole, and a dipole isn't any more "good for E fields" than a loop. See my posting of about 3 days ago in this newsgroup in the thread "Re: Loop vx Folded Dipole noise factor".

Second, the E field isn't 120 * pi stronger than the H field. In free space, in the far field from the source, the E field is 120 * pi OHMS times the H field. You could say one is stronger than the other only if they had the same units, which they don't. A parallel to this would be to say that the voltage is "stronger" than the current in a 10 ohm resistor, but "weaker" in a 0.1 ohm resistor. Voltage and current are different things, just as E and H fields are, so can't be directly compared for "strength".

You might want to dust off the fields text you used in your EE curriculum, and review the relationship between E and H fields, and what happens when they interact with an antenna.

Hi OM,

Umm, not my source (although my cohort). Check with John Ciardi's
"Good Words to You." He follows you closer, but there is no
"noncarborundum." As many of John's entries derive from the military,
I bet this one does too (which is where I heard it first 35 years ago
anyway).

Ask the current US president about radio receivers hidden under ill-fitting suits. I believe that he has some recent hands-on experience with the subject...

This seems to be a trivial problem. Any old 6-inch wire should work. If not, why not use a higher gain antenna at the "server" end of the link? Also - police "wires" (mics) work, you shouldn't have any problems.

A googling will reveal several varients. A somewhat scholarly
discussion and a theory as to its origins can be found at
http://alt-usage-english.org/excerpts/fxillegi.html

I first heard it forty years ago when I was in college {English/French
major, not engineer}.

The discussion above credits General "Vinegar Joe" Stillwell as
popularizing the phrase when he gestingly took it as his motto.
The second time I heard it was from a famous cryptologist who actually
was on Stillwell's staff during WW II. [BTW I was a not-so-famous
cryptologist in my working life.]
The writer of the discussion attributes the phrase to British
Intelligence in WW II and having worked with these guys, I could
certainly believe it.

Attenation Yaesu Equipment Owners.
You are invited to join us at Fox Tango International at Yahoo groups.
http://groups.yahoo.com/group/FoxTango/

Please Visit our Web site at
Http://www.foxtango.org

"I am writing to suggest that you join with me an other owners of the Yaesu FT-101 in an informal association which we might call the Fox-Tango Group. It would serve as a sort of benovelent, protective, mutual aid and perhaps social club, essentially for the purpose of interchanging information, ideas, experiences and problems"

These were the words of Milton Lowens (N4ML) when he started the Fox Tango Club in 1972, which was dedicated to the exchange of information about the Yaesu FT-101 amateur radio transceiver. The club published the FT Newsletter from 1972 until 1985. I was a member of the Fox Tango Group from 1977 to 1985. I still remember that I could hardly wait to receive each month's issue of the Fox Tango Newsletter jam packed with modifications and user suggestions for my beloved FT-101.

In an effort to keep the Fox Tango flame burning and continue the interchange of information to enhace the effectiveness of these old rigs. I invited you to join the Fox Tango Club at Yahoo goups.

Topics of discussion will cover the FT-101, FT-101B, FT-101E, through the FT-101F, FL-2100B including all Yaesu accesories. Yaesu Twins FR-101, FL-101, FT-620B, FT-220, FT-221, FT-101ZD, FL-2100Z, FT-901, FT-901DM, FT-920 FT-102, FT-757Gx, GXII, FT-767, FT-7, FT-7B, FT-227R, CPU-2500R and other more recent models such as the FT-100D FT-1000D.

Welcome to the International Fox Tango Club at Yahoo Groups.

Organized 1971 By & For Owners of Yaesu Equipment
For more information about Fox Tango International please
visit the Fox Tango Web Page at Foxtango.org
Or the Link provided below.

Language corruption isn't always bad. Just a few nights ago I was listening to the BBC World Service (rebroadcast here on public radio). A (British) lady was expounding about the troubles of some American government officials and their illegal-alien nannies. When asked if she had a nanny, she hesitated, then said she did. And she added that any revelation of impropriety on her behalf would be very "red-facening".

I thought it was, well, you know, like, whatever.

What gives you the impression the E field is stronger than the H field?

Why not give the fields a strength in numbers so that you can compare the two.

To make a true comparison you should use the same strength measurement units for both.

Any noun can be verbed. Any verb is subject to abusage.

Then there's The Adjectival Superlative of the Present Participle, as overheard at a music festival the USA: "These are the dancingest folks."

But the booze writers surely cap it all. We've just been given something that offers "a superbly sweet and peaty island experience on the nose" and promises "a lingering peaty finale." It takes real artistry to write like that... and much more nerve than I possess.

Happy Holidays!

There is only one Field which has components.

Most likely, the source of such widespread defective reasoning lies in the curriculum.

It's the same with SWR meters and PA conjugate matches. ;o)

Nonsense! AM radio stations can be heard for thousands of miles, FM for
'line of sight', which is usually less than a hundred miles.

> however it's
> limited to line-of-sight. However, when you're 40,000 feet up you can

Nonsense! The passenger is sitting in a Faraday Cage, a fuslage made of
alumninum. The FM wavelength is short enough to go thru the windows,
but mot the AM signals.

If you stretch a string on a globe from London to Florida, it will show
the 'great circle' route that's the shortest, and that should be your
plane's path, barring storme, hurricanes, etc. You'll see that it comes
really close to the eastern Canadian provinces.

If you make your own TRF receiver, with no LO, it won't interfere with
anything. In fact, you can then put an AM detector in it, and also
listen to the aircraft chatter.

Another way is to listen to stations at or below 97.3 MHz, which would
keep the LO at 108 MHz or below.

No, the laws say that you can be arrested for breaking them, and one way
to break them is to use a FM radio while the aircraft is flying.

You don't know what you're talking about. With the attitudes of the air
marshals nowadays, making airliners turn around and go back to their
departure point just because a passenger is unruly, there is a high
probability that one of them is flying along on your flight, and if he
sees an earphone hanging out of your ear, you might be that unruly
passenger they arrest at the departure point. Especially with your
nasty attitude!

> What about my hand-held GPS unit? Any chance me using it (during all

How come I never saw the original post?

In any case, Antennas IS the PROPER Plural form of the word when used in reference to: a metallic device (as a rod or wire) for sending out or receiving radio waves.

Antennae is plural for the word when used in reference to an arthropod.

Now if your Antenna is covered with growing mildew and moss, I guess Antennae's would be the more appropos choice, hi hi.....

To my delight, I received a Grundig AM/FM/SW radio for Christmas. I have been wanting a radio like this for some time. Now what I need to do is construct an external loop antenna because I will be using the radio in my office and I need to get better reception. The best I can do is locate the antenna inside the building. Can anyone give me information or steer me to a good website for loop antenna plans? I'm really most interested in the medium wave band to 120m band area.

Don

If a word is used spelled or defined incorrectly by enough people for a long enough period of time it likely will become considered by those who make the rules to now be considered the correct usage spelling or definition and perhaps by the time that this marathon of absolute correctness of usage thread ends the word may well have in fact changed anyway and I hope you all have a gay Xmas.

BTW feel free to argue about the commas in my sentence... ;)

My only thought is, feed it with balanced line and take the time to
investigate a balanced line tuner, for reception only you can make one
quite easily, you can significantly null noise sources (at times)
and I think for 120m it would enhance the performance.

It's 10.00 hrs, Xmas Day.

"George" is the nicest-sounding name in morse code. Its really rythmic and sings.

I sometimes wish I'd been christened "George".

I once had a great-uncle George. He had been in South Africa in the Boer War. But he wasn't a radio amateur.

He was in the artillery. When I was a boy he told me that if one stood immediately behind the breech of a 28-pounder one could actually see the shell leave the barrel and follow its trajectory.

Now I remember this little technical detail because, as a boy, I thought it rather unfair, not at all cricket, to use cannon against people armed with spears and wicker shields.

I later realised the enemy were only unarmed European immigrants being rounded-up for the newly-invented concentration camps, Dutch in fact, who had no more right to be there than Uncle George had. That made things alright.

Ah for the days when Britannia Ruled the Waves.

So now for the festivities!

Message-ID: <3358hdF3t5e1kU1@individual.net>
Source record: 84815

The real plural, from its Latin root is, "antennae".

The Latin word meant a yardarm for a sail, but in those
days sails were not square rigged but lateen types. Hence
it seemed a good analogy to use the word for feelers of insects.

(The etymological entymological derivation is thus not
the original)

Those who are ignorant about the English Language and its
etymology, especially the Yanks and nerdy types, have
introduced the erroneous plural, "antennas".

Language changes, but where an obvious error has been introduced
by the ignoramuses of this World, there is no harm in correcting
the error and using, "antennae" henceforth. Let those who are CBers
and CBers-Masquerading-As-Radio-Hams identify themselves by
continuing with the use of the uneducated errneous plural!

And never start a sentence with a conjunction.

Don't never use double negatives.

A preposition is not something to end a sentence with.

Eschew obfuscation.

Single word sentences? Don't!

Even if a mixed metaphor sings, it should be derailed.

etc, etc.

No. Antennae is the proper plural.

Antennas is used by those who are ignorant about the
English language such as nerdy geeks and Yanks.

The OED gives "antennae" as the correct plural, with "antennas"
as an alternative.

Reg, the Boers were anything but unarmed. Asymmetrical warfare and all that.
Further, they were European emigrants, not immigrants. They were, however,
African immigrants. At that time, Britain did rule the waves, but Tommy had
got off the boat and gone a long way inland. BTW, did George tell you that
you could see the trajectory equally well from in front of the muzzle?

>
>Ah for the days when Britannia Ruled the Waves.

To wit: The words of W.S. Gilbert on this subject.

THE HOUSE OF PEERS

When Britain really ruled the waves--
(In good Queen Bess's time)
The House of Peers made no pretence
To intellectual eminence,
Or scholarship sublime;
Yet Britain won her proudest bays
In good Queen Bess's glorious days!

When Wellington thrashed Bonaparte,
As every child can tell,
The House of Peers, throughout the war,
Did nothing in particular,
And did it very well;
Yet Britain set the world ablaze
In good King George's glorious days!

And while the House of Peers withholds
Its legislative hand,
And noble statesmen do not itch
To interfere with matters which
They do not understand,
As bright will shine Great Britain's rays,
As in King George's glorious days!

From "Iolanthe"

For an opposing view on the beauty of "George" see the writings of
George Bernard Shaw on the subject. He hated his given name,
wrote it down phonetically [jorj] and thought that was most ugly.
I suspect he didn't use it in Morse very much. Shaw also
came up with "ghoti" for "fish"

The "gh" from "rough"
the "o" from "women"
the "ti" from any "-tion" suffix.

I suppose no one called him "Bernie."

In long range rifle shooting, one can see the bullet's trajectory curve into the wind before striking the target. A second person to watch the travel is sometimes needed when the wind is especially hard to "read."

Once in a great while, one can see the bullet explode before getting to the target - presumably because of asymmetry of the bullet itself.

Uncle George had a more easy time seeing his shells.

Wish radio waves could be seen.

Received Kraus 3rd for Christmas. Even more lucid that Kraus 1st, which got me started decades ago. A must have book.

Merry Christmas & 73 Mac N8TT

I am using a G5RV and an Icom 756Pro II. The auto antenna tuner will tune the antenna fine except in the area of 3963.5 and up to at least 4.0385. I use 4.0385 as a member of MARS. Right now my SWR "as shown" is well into the "red zone".

Is there any way to modify the antenna to get it to be a better match so that the auto tuner can do its thing. The antenna is the shortened or Jr. version with a ladder wire lead in.

Would changing the lead in to RG8 coax be a help??

Sure will appreciate some help. I am a novice at this and it is important that I am able to use 4.083.5.

# 4135. Base Antenna for CB Radio

Source record: 84732

I skimmed over the ARRL antenna book. From there i understand, that an antenna is either complete (dipole) or it relies on ground, either natural or artificial (counterpoise, radials).

Given that, i wonder what to think about a half wave antenna like the SOLARCON ANTRON 99 without radials.

Most of these antennas have an included 1:9 matcher, why?

How does such an antenna work anyway? Is there no ground required to operate such an antenna? How can they work without ground?

Regars,
Johann

The OED does not prescribe nor proscribe English, it describes it by
historical usage. For instance, the RF usage for antenna|e did not
enter the language until 1902 - the same time "aerial wire" appeared;
but whose adjective has since been promoted to the substantive when
radios(US 1915) became "wireless"(1904).

If it doesn't have to be an all band antenna, I would change to a coax
fed half wave dipole. You wouldn't need a tuner,
except to drop farther down the band, and your efficiency would
be high. To work all bands using the ladder line, I would get a
good external tuner. But the coax fed dipole will have the better
signal on 75m by a noticable amount over the jr-g5rv. The internal
radio
tuners are not really meant to match ladder line fed antennas. I
wouldn't
try to load anything over about a 5:1 mismatch with one myself. I
consider
them as "line flatteners" mainly. IE: good to provide a wider usable
bandwidth, with an already half decent match. MK

No leg pull intended. My IC-706 and ClearSpeech speaker work
unbelievably well on AM talk radio which is what I listen to
on AM. My home town has extremely noisy power lines. The
ClearSpeech speaker takes that all out.....................

I like the MW on the 706mk2g. Has good audio, and is just the right
width for "general use". It's fairly wide stock, which is good for MW.
Sounds a lot better than the ham rig with only tight 4.8kc AM
filtering,
using the stock SSB filter. Using the 44 inch per side loop I have in
here, it works great. But it also works good on MW mobile just using my

ham antenna tuned to a lower band...Doesn't have to really be tuned to
resonance..Plenty of signal with the antenna set for 80m. But my trucks
also have radios...The ac-delco I have in one truck is real good, but
I've never really tested the other "whatever brand" with the tape deck,

etc. Actually, offhand, I don't think it's that good, but it might be
the antenna , or the trimmer in the radio being off. If I listen to MW
in the house, it's almost always on the 706 these days. MK

string around and across so that he looks like
he?s crawling.
Glaze, then arrange pineapples and secure with cloves.
Bake uncovered in 350° oven till thermometer reaches 160°.

Cajun Babies

Just like crabs or crawfish, babies are boiled alive!
You don?t need silverware, the hot spicy meat comes off in your hands.

6 live babies
1 lb. smoked sausage
4 lemons
whole garlic
2 lb. new potatoes
4 ears corn
1 box salt
crab boil

Bring 3 gallons of water to a boil.
Add sausage, salt, crab boil, lemons and garlic.
Drop potatoes in, boil for 4 minutes.
Corn is added next, boil an additional 11 minutes.
Put the live babies into the boiling water and cover.
Boil till meat comes off easily with a fork.

Oven-Baked Baby-Back Ribs

Beef ribs or pork ribs can be used in this recipe,
and that is exactly what your dinner guests will assume!
An excellent way to expose the uninitiated to this highly misunderstood
yet succulent source of protein.

2 human baby rib racks
3 cups barbecue sauce or honey glaze (see index)
Salt
black pepper
white pepper
paprika

Remove the silverskin by loosening from the edges,
then stripping off.
Season generously, rubbing the mixture into the baby?s flesh.
Place 1 quart water in a baking pan, the meat on a wire rack.
Bake uncovered in 250° oven for 1° hours.

When browned, remove and glaze,
return to oven and bake 20 minutes more to form a glaze.
Cut ribs into individual pieces and serve with extra sauce.

Fre

The problem is a resonant 1/2 wave dipole at the high end of 75 meters
is about 115-120 feet long. At 51 feet, your g5rv jr is less than a
quarter wavelength long at the desired frequencies. What is the
longest dipole you can put up (even if you zig-zag it and make it
crooked)?

==========

Long live "Iolanthe" and all the many other often underated G & S operas.

I'm pleased to make a brief acquaintance with a fiddler familiar with the works of Gilbert & Sullivan, which pair contributed in the long term far more to the world of song and music than the Beatles. Incidentally, I didn't fully appreciate the Beatles until after they had split up. No doubt, some of their works, although relatively brief, will eventually be placed alongside the works of Beethoven.

George Bernard Shaw wrote about the world in a far more serious manner than the humorous, entertaining Gilbert. There's much to be leaned from both. But GBS was a serious teacher in addition to being a playwrite. More serious even than Shakespeare who was a sort of early Socialist.

Incidentally, it was Henry the Eighth's (six wives) Dissolution of the Monastries which paid for the fleet of pirate ships available to Queen Elizabeth 1st's navy. So began the British Empire on which the sun never set.

And what sort of mess, based on piracy, have us English left behind in our wake.?

Well, there's always the City of London and Wall Sreet.

But unfortunately similarly based.
---
Reg.

Roast Leg of Amputee

By all means, substitute lamb or a good beef roast if the haunch
it is in any way diseased. But sometimes surgeons make mistakes,
and if a healthy young limb is at hand, then don?t hesitate to cook
it to perfection!

1 high quality limb, rack, or roast
Potatoes, carrot
Oil
celery
onions
green onions
parsley
garlic
salt, pepper, etc
2 cups beef stock

Marinate meat (optional, not necessary with better cuts).
Season liberally and lace with garlic cloves by making incisions,
and placing whole cloves deep into the meat.
Grease a baking pan, and fill with a thick bed of onions,
celery, green onions, and parsley.
Place roast on top with fat side up.
Place uncovered in 500° oven for 20 minutes, reduce oven to 325°.
Bake till medium rare (150°) and let roast rest.
Pour stock over onions and drippings, carve the meat and
place the slices in the au jus.

I believe the A99 is an end fed half wave vertical. This type antenna
does not have to rely on a ground plane to provide an ï¿½imageï¿½ like a 1/4
wavelength vertical and it would need something to match itï¿½s very high
impedance, possibly what they refer to as a 1:9 matcher. The performance
should be similar to a 1/2 wave dipole but the manufacturers of these
type antennas advertise spectacular gains, donï¿½t believe them. I used
one for a while on 10m and it works ok, nothing special but they are
cheap and easy to install.
Mike

Sounds like rhetoric in place of argument. As I said, the original
Greek is found in the OED - if, of course, you speak from its
authority and you have access, otherwise your response is called
"winging it" (vulgar US colloq. ca. 20th cent.) ;-)

The Greek (this is from the OED by the way) was translated by
Theodosius, the Monophysite monk (d. 1478 Gaza). By the way, for
English there is no earlier usage of Antenna|e than 1698.

From Weekly:
"Greek is recorded, in the Homeric poems, from the 7th century
B.C. It was divided into a number of dialects - Ionic, Doric,
Aeolic, Attic - the last of which eventually prevailed and still
exists, not greatly changed, as Modern Greek. Its direct
contribution to English does not begin till the Renaissance,
but the coinage of scientific and philosophical terms of
Greek origin is now continuous."

(it is cheaper and better to
cut up a whole roast than to buy stew meat).

1 stillbirth, de-boned and cubed
&#65533; cup vegetable oil
2 large onions
bell pepper
celery
garlic
&#65533; cup red wine
3 Irish potatoes
2 large carrots

This is a simple classic stew that makes natural gravy,
thus it does not have to be thickened.
Brown the meat quickly in very hot oil, remove and set aside.
Brown the onions, celery, pepper and garlic.
De-glaze with wine, return meat to the pan and season well.
Stew on low fire adding small amounts of water and
seasoning as necessary.
After at least half an hour, add the carrots and potatoes,
and simmer till root vegetables break with a fork.
Cook a fresh pot of long grained white rice.

Pre-mie Pot Pie

When working with prematurely delivered newborns (or chicken) use sherry;
red wine with beef (buy steak or roast, do not pre-boil).

Pie crust (see index)
Whole fresh pre-mie; eviscerated, head, hands and feet removed
Onions, bell pepper, celery
&#65533; cup wine
Root vegetables of choice (turnips, carrots, potatoes, etc) cubed

Make a crust from scratch - or go sha

peppers, and celery (all chopped finely)
and season well.
Place in a large bowl and cool.
Add seasoned breadcrumbs and a little of the tomato gravy,
enough to make the mixture pliable.
Divide the stuffing among the cabbage leaves then roll.
Place seam down in a baking pan.
Ladle tomato gravy on top,
and bake at 325&#65533; for 30 - 45 minutes.

```
Umbilical Cordon Bleu

Nothing is so beautiful as the bond between mother and child,
so why not consume it?
Children or chicken breasts will work wonderfully also.

4 whole umbilical chords (or baby breasts, or chicken breasts)
4 thin slices of smoked ham, and Gruyere cheese
Flour
eggwash (milk and eggs)
seasoned bread crumbs
1 onion
minced
salt
pepper
butter
olive oil
```

Pound the breasts flat (parboil first if using umbilical
cords so they won?t be tough).
Place a slice of ham and cheese on each, along with some minced onion
then fold in half, trimming neatly.
Dredge in flour, eggwash, then seasoned breadcrumbs;
allow to sit for a few minutes.
Saut&#65533; in butter and olive oil until golden brown,
about 6 minutes on each side.

```
Shish Kababes

As old as the hills, this technique has employed seafood, beef, pork, lamb,
poultry, and vegetables; just about anything can be grilled, and young humans
are no exception!

High quality marinade (Teriyaki and garlic perhaps)
1 inch cubes of tender meat, preferably from the nursery
```

Onions
bell peppers
Wooden or metal skewers

Marinate the meat overnight.
Get the grill goo

fresh cracked black pepper

Season and saut&#65533; the cutlets in olive oil till golden brown, remove.
Add the garlic and onions and cook down a bit.
Add some lemon juice and some zest, then de-glaze with stock.
Add a little cornstarch (dissolved in cold water) to the sauce.
You are just about there, Pour the sauce over the cutlets,
top with parsley, lemon slices and cracked pepper.
Serve with spinach salad, macaroni and cheese (homemade) and iced tea...

Spaghetti with Real Italian Meatballs

If you don?t have an expendable bambino on hand,
you can use a pound of ground pork instead.
The secret to great meatballs, is to use very lean meat.

1 lb. ground flesh; human or pork
3 lb. ground beef
1 cup finely chopped onions
7 - 12 cloves garlic
1 cup seasoned bread crumbs
&#65533; cup milk, 2 eggs
Oregano
basil
salt
pepper
Italian seasoning, etc.
Tomato gravy (see index)

Fresh or at least freshly cooked spaghetti or other pasta

Mi

if a healthy young limb is at hand, then don?t hesitate to cook
it to perfection!

1 high quality limb, rack, or roast
Potatoes, carrot
Oil
celery
onions
green onions
parsley
garlic
salt, pepper, etc
2 cups beef stock

Marinate meat (optional, not necessary with better cuts).
Season liberally and lace with garlic cloves by making incisions,
and placing whole cloves deep into the meat.
Grease a baking pan, and fill with a thick bed of onions,
celery, green onions, and parsley.
Place roast on top with fat side up.
Place uncovered in 500&#65533; oven for 20 minutes, reduce oven to 325&#65533;.
Bake till medium rare (150&#65533;) and let roast rest.
Pour stock over onions and drippings, carve the meat and
place the slices in the au jus.

Bisque &#65533; l?Enfant

Honor the memory of Grandma with this dish by utilizing her good
silver soup tureen and her great grandchildren (crawfish, crab or
lobster will work just as well, however this dish is classically
made with crawfish).

Stuffed infant heads, stuffed crawfish heads, stuffed crab or lobster shells;
make patties if shell or head is not available
(such as with packaged crawfish, crab, or headless baby).
Flour
oil
onions
bell peppers
garlic salt, pepper, etc.
3 cups chicken stock
2 sticks butter
3 tablespoons oil

First stuff the heads, or make the patties (see index)
then fry or bake.
Set aside to drain on paper towels.
Make a roux with butter, oil and flour,
brown vegetables in the roux, then add chicken stock and
allow to simmer for 20 minutes.
Add the patties or stuffed heads, and some loose crawfish,
lobster, long piglet, or what have you.
Cook on low for 15 minutes, then allow it to set for at least
15 minutes more.
Serve over steamed rice; this dish is very impressive!

Stuffed Cabbage Rolls

Babies really can be found

have lots of meat
(of course this can consist of chicken, beef, pork, or shrimp).
Who can resist this classic appetizer; or light lunch served with
a fresh salad? Versatility is probably this recipe?s greatest virtue,
as one can use the best part of a prime, rare, yearling, or the
morticians occasional horror: a small miracle stopped short by a
drunk driver, or the innocent victim of a drive-by shooting...

2 cups finely chopped very young human flesh
1 cup shredded cabbage
1 cup bean sprouts
5 sprigs green onion, finely chopped
5 cloves minced garlic
4-6 ounces bamboo shoots
Sherry
chicken broth
oil for deep frying (1 gallon)
Salt
pepper
soy & teriyaki
minced ginger, etc.
1 tablespoon cornstarch dissolved in a little cold water
1 egg beaten

Make the stuffing:
Marinate the flesh in a mixture of soy and teriyaki sauces
then stir fry in hot oil for till brown - about 1 minute, remove.
Stir-fry the vegetables.
Put the meat back into the wok and adjust the seasoning.
De-glaze with sherry, cooking off the alcohol.
Add broth (optional) cook a few more minutes.
Add the cornstarch, cook a few minutes till thick,
then place the stuffing into a colander and cool;
2 hours
Wrap the rolls:
Place 3 tablespoons of stuffing in the wrap, roll tightly -
corner nearest you first, fold 2 side corners in,
wrap till remaining corner is left.
Brush with egg, seal, and allow to sit on the seal for
a few minutes.
Fry the rolls:

Southern Fried Small-fry

Tastes like fried chicken, which works just as well.
In fact you may want to practice cutting up whole chickens
for frying before you go for the real thing.
Whole chicken is much more efficient and inexpensive than buying pieces.

1 tiny human, cut into pieces
2 cups flour
Onion, garlic
Salt
pepper
garlic powder
cayenne pepper
hot sauce, etc.
Oil for frying

Mix milk, eggs, hot sauce in a bowl, add chopped onion and garlic.
Season the meat liberally, and marinate for several hours.
Place seasoned flour in a paper or plastic shopping bag,
drop pieces in a few a time, shake to coat thoroughly,
then deep fry in hot oil (350°) for about 15 minutes.
Drain and place on paper towels.

Miscarriage with Mustard Greens

Why waste it? Otherwise, and in general, use ham or salt pork to season greens.
The technique of smothering greens can be used with many vegetables;
green beans work especially well. Meat is not necessary every day, don?t
be afraid to alter any dish to vegetarian tastes.

1 premature baby, born dead
Large bunch of mustard greens
2 white onions, 1 cup chopped celery
Vegetable oil (or hog fat)
Salt, pepper, garlic, etc.

Lightly brown onions, celery, garlic and meat in large heavy pot.
Add a little water and the greens (which should be thoroughly cleaned and washed).
Smother slowly for at least 2 hours, adding small amounts of water
when it starts to stick.
Stir frequently.
When ready - serve with rice, grilled smoked sausage, green salad, and iced tea.
Coffee and apple pie then brandy.

Maternity Ward Pot Luck Dinner

If you can?t get anything fresh from the hospital, nursery, or morgue;
you can at least get rid of all the leftovers in your refrigerator.

1 - 2 lbs. cubed meat (huma

or pork
3 lb. ground beef
1 cup finely chopped onions
7 - 12 cloves garlic
1 cup seasoned bread crumbs
 cup milk, 2 eggs
Oregano
basil
salt
pepper
Italian seasoning, etc.
Tomato gravy (see index)
Fresh or at least freshly cooked spaghetti or other pasta

Mix the ground meats together in a large bowl,
then mix each of the other ingredients.
Make balls about the size of a baby?s fist
(there should be one lying around for reference).
Bake at 400for about 25 minutes -
or you could fry them in olive oil.
Place the meatballs in the tomato gravy, and simmer for several hours.
Serve on spaghetti.
Accompany with green salad, garlic bread and red wine.

Newborn Parmesan

This classic Sicilian cuisine can easily be turned into Eggplant Parmesan
If you are planning a vegetarian meal. Or you could just as well use veal -
after all, you have to be careful - Sicilians are touchy about their young
family members...

6 newborn or veal cutlets
Tomato gravy (see index)
4 cups mozzarella, 1cup parmesan, 1cup romano
Seasoned bread crumbs mixed with
parmesan
romano
salt
pepper
oregano
garlic powder
chopped parsley
Flour
eggwash (eggs and milk)

Peanut oil for frying.

Pound the cutlets.
Dredge in flour, eggs, then the bread crumb mixture.
Fry till golden brown in 350° peanut oil.
In a baking pan, place a layer of gravy,
then one of meat, gravy, and cheese.
Another layer each of meat, gravy, and cheese.
Then bake at 350° for 45 minutes.
Serve on hot pasta with romano cheese.

Southern Fried Small-fry

Tastes like fried chicken, which works just as well.
In fact you may want to practice cuttin

are eating
human babies, this is the perfect solution.
But if you are still paranoid, you can substitute pork butt.

5 lb. lean chuck roast
3 lb. prime baby butt
2 tablespoons each:
salt
black, white and cayenne peppers
celery salt
garlic powder
parsley flakes
brown sugar
1 teaspoon sage
2 onions
6 cloves garlic
bunch green onions, chopped

Cut the children?s butts and the beef roast into pieces
that will fit in the grinder.
Run the meat through using a 3/16 grinding plate.
Add garlic, onions and seasoning then mix well.
Add just enough water for a smooth consistency, then mix again.
Form the sausage mixture into patties or stuff into natural casings.

Stillborn Stew

By definition, this meat cannot be had altogether fresh,
but have the lifeless unfortunate available immediately after delivery,
or use high quality beef or pork roasts (it is cheaper and better to
cut up a whole roast than to buy stew meat).

1 stillbirth, de-boned and cubed
&#65533; cup vegetable oil
2 large onions
bell pepper
celery
garlic
&#65533; cup red wine
3 Irish potatoes
2 large carrots

This is a simple classic stew that makes natural gravy,

Forget all about a G5RV. No sooner you modify it, it will no longer be a G5RV. It was designed to be useful with an easy impedance match only at 14.15 MHz On other bands it cannot be no better, and is usually worse, than any other random length supposedly multiband dipole.

All you have to do, to obtain the best possible mutliband dipole for your back yard, is to erect a high dipole of any length which conveniently fits into your backyard, fed via a 450-ohm or 600-ohm transmission line, of no particular lemgth. The most important component in the system is the Tuner. Invest in the tuner. It will last you for years on all bands. Ideally, have one tuner for 10 to 30 Mhz and another for 1.8 to 7.5 MHz. You wont regret it for multiband operation.

Maternity Ward Pot Luck Dinner

If you can?t get anything fresh from the hospital, nursery, or morgue;
you can at least get rid of all the leftovers in your refrigerator.

1 - 2 lbs. cubed meat (human flesh, chicken, turkey, beef...)
1 -2 lbs. coarsely chopped vegetables
(carrots, potatoes, turnips, cauliflower, cabbage...)
Bell pepper
onions
garlic
ginger
salt pepper, etc.
Olive oil
butter

Brown the meat and some chopped onions, peppers, and garilic in olive oil,
place in baking dish, layer with vegetables seasoning and butter.
Bake at 325&#65533; for 30 - 45 minutes.
Serve with hot dinner rolls, fruit salad and sparkling water.

B&#65533;b&#65533; Buffet 1

Show off with whole roasted children replete with apples in mouths -
and babies? heads stuffed with wild rice. Or keep it simple with a
hearty main course such as stew, lasagna, or meat loaf.

Some suggestions

Pre-mie pot pies, beef stew, leg of lamb, stuffed chicken, roast pork spiral ham,

Leviticus 26:29

Roast Child with Cornbread Stuffing

Turkey may be substituted for this classic holiday feast.
Although time consuming, this dish seems to take longer than it actually does;
as the entire house is filled with such a heavenly aroma,
the waiting becomes almost unbearable.

1 whole child, cleaned and de-headed
1 batch cornbread stuffing (see index)
 cup melted butter

Remove the giblets from the infant and set aside.
Stuff the cavity where the child?s genitals and anus were located
using  cup per pound of meat.
Tie the arms flat to the body, then pull the skin flaps up to close the cavity.
Now tie the thighs up tight to hold it all together.
Place breast side up in a large metal roasting pan.
Bake in 325 oven covered for 2 hours.
Remove cover, stick a cooking thermometer deep into one of the
baby?s buttocks and cook uncovered till thermometer reads 190,
about another hour.

Pro-Choice Po-Boy

Soft-shelled crabs serve just as well in this classic southern delicacy.
The sandwich originated in New Orleans, where an abundance of abortion clinics
thrive and hot French bread is always available.

2 cleaned fetuses, head on
2 eggs
1 tablespoon yellow mustard
1 cup seasoned flour
oil enough for deep frying
1 loaf French bread
Lettuce
tomatoes
mayonnaise, etc.

Marinate the fetuses in the egg-mustard mixture.
Dredge thoroughly in flour.
Fry at 375 until crispy golden brown.
Remove and place on paper towels.

Holiday Youngster

One can easily adapt this recipe to ham, though as presented,
it violates no religious taboos against swine.

1 large toddler or small child, cleaned and de-headed
Kentucky Bourbon Sauce (see index)
1 large can pineapple slices
W

onions
bell pepper
celery
garlic
&#65533; cup red wine
3 Irish potatoes
2 large carrots

```
This is a simple classic stew that makes natural gravy,
thus it does not have to be thickened.
Brown the meat quickly in very hot oil, remove and set aside.
Brown the onions, celery, pepper and garlic.
De-glaze with wine, return meat to the pan and season well.
Stew on low fire adding small amounts of water and
seasoning as necessary.
After at least half an hour, add the carrots and potatoes,
and simmer till root vegetables break with a fork.
Cook a fresh pot of long grained white rice.

Pre-mie Pot Pie

When working with prematurely delivered newborns (or chicken) use sherry;
red wine with beef (buy steak or roast, do not pre-boil).
```

Pie crust (see index)
Whole fresh pre-mie; eviscerated, head, hands and feet removed
Onions, bell pepper, celery
&#65533; cup wine
Root vegetables of choice (turnips, carrots, potatoes, etc) cubed

```
Make a crust from scratch - or go shamefully to the frozen food section
of your favorite grocery and select 2 high quality pie crusts (you
will need one for the top also).
Boil the prepared delicacy until the meat starts to come off the bones.
Remove, de-bone and cube; continue to reduce the broth.
Brown the onions, peppers and celery.
Add the meat then season, continue browning.
De-glaze with sherry, add
```

# 4172. Re: Using a Loop Antenna

rice; this dish is very impressive!

Stuffed Cabbage Rolls

Babies really can be found under a cabbage leaf -
or one can arrange for ground beef to be found there instead.

8 large cabbage leaves
1 lb. lean ground newborn human filets, or ground chuck
Onions
peppers
celery
garlic
soy sauce
salt pepper, etc
Olive oil
breadcrumbs
Tomato Gravy (see index)

Boil the cabbage leaves for 2 minutes to soften.
In skillet, brown the meat in a little olive oil,
then add onions, peppers, and celery (all chopped finely)
and season well.
Place in a large bowl and cool.
Add seasoned breadcrumbs and a little of the tomato gravy,
enough to make the mixture pliable.
Divide the stuffing among the cabbage leaves then roll.
Place seam down in a baking pan.
Ladle tomato gravy on top,
and bake at 325° for 30 - 45 minutes.

Umbilical Cordon Bleu

Nothing is so beautiful as the bond between mother and child,
so why not consume it?
Children or chicken breasts will work wonderfully also.

4 whole umbilical chords (or baby breasts, or chicken br

top crust and with a fork, seal the crusts together
then poke holes in top.
Return to oven and bake for 30 minutes, or until pie crust is golden brown.

Sudden Infant Death Soup

SIDS: delicious in winter, comparable to old fashioned Beef and Vegetable Soup.
Its free, you can sell the crib, baby clothes, toys, stroller... and so easy to
procure if such a lucky find is at hand (just pick him up from the crib and
he?s good to go)!

SIDS victim, cleaned
 cup cooking oil
Carrots
onions
broccoli
whole cabbage
fresh green beans
potato
turnip
celery
tomato
 stick butter
1 cup cooked pasta (macaroni, shells, etc.)

Remove as much meat as possible, cube, and brown in hot oil.
Add a little water, season, then add the carcass.
Simmer for half an hour keeping the stock thick.
Remove the carcass and add the vegetables slowly to the stock,
so that it remains boiling the whole time.
Cover the pot and simmer till vegetables are tender
(2 hours approximately).
Continue seasoning to taste.
Before serving, add butter and pasta,
serve piping with hot bread and butter.

Offspring Rolls

Similar to Vietnamese style fried rolls, they have lots of meat
(of course this can consist of chicken, beef, pork, or shrimp).
Who can resist this classic appetizer; or light lunch served with
a fresh salad? Versatility is probably this recipe?s greatest virtue,

etc.
Tomato gravy (see index)
Fresh or at least freshly cooked spaghetti or other pasta

Mix the ground meats together in a large bowl,
then mix each of the other ingredients.
Make balls about the size of a baby?s fist
(there should be one lying around for reference).
Bake at 400°for about 25 minutes -
or you could fry them in olive oil.
Place the meatballs in the tomato gravy, and simmer for several hours.
Serve on spaghetti.
Accompany with green salad, garlic bread and red wine.

Newborn Parmesan

This classic Sicilian cuisine can easily be turned into Eggplant Parmesan
If you are planning a vegetarian meal. Or you could just as well use veal -
after all, you have to be careful - Sicilians are touchy about their young
family members...

6 newborn or veal cutlets
Tomato gravy (see index)
4 cups mozzarella, 1cup parmesan, 1cup romano
Seasoned bread crumbs mixed with
parmesan
romano
salt
pepper
oregano
garlic powder
chopped parsley
Flour
eggwash (eggs and milk)
Peanut oil for frying.

Pound the cutlets.
Dredge in flour, eggs, then the bread crumb mixture.
Fry till g

Pound the cutlets.
Dredge in flour, eggs, then the bread crumb mixture.
Fry till golden brown in 350° peanut oil.
In a baking pan, place a layer of gravy,
then one of meat, gravy, and cheese.
Another layer each of meat, gravy, and cheese.
Then bake at 350° for 45 minutes.
Serve on hot pasta with romano cheese.

Southern Fried Small-fry

Tastes like fried chicken, which works just as well.
In fact you may want to practice cutting up whole chickens
for frying before you go for the real thing.
Whole chicken is much more efficient and inexpensive than buying pieces.

1 tiny human, cut into pieces
2 cups flour
Onion, garlic
Salt
pepper
garlic powder
cayenne pepper
hot sauce, etc.
Oil for frying

Mix milk, eggs, hot sauce in a bowl, ad

egg roll wraps, 350&#65533; for spring roll wraps.
Deep fry in peanut oil till crispy golden brown, drain on paper towels.

Lemon Neonate

Turkey serves just as well, and in fact even looks a bit like a well-dressed baby. By the time you turn the child?s breast into cutlets, it will be indistinguishable. The taste of young human, although similar to turkey (and chicken) often can be wildly different depending upon what he or she has consumed during its 10 to 14 months of life...

4 well chosen cutlets (from the breasts of 2 healthy neonates)
2 large lemons (fresh lemons always, if possible)
Olive oil
Green onions
Salt
pepper
cornstarch
neonate stock (chicken, or turkey stock is fine)
garlic
parsley
fresh cracked black pepper

Season and saut&#65533; the cutlets in olive oil till golden brown, remove.
Add the garlic and onions and cook down a bit.
Add some lemon juice and some zest, then de-glaze with stock.
Add a little cornstarch (dissolved in cold water) to the sauce.
You are just about there, Pour the sauc

to coat thoroughly,
then deep fry in hot oil (350&#65533;) for about 15 minutes.
Drain and place on paper towels.

Miscarriage with Mustard Greens

Why waste it? Otherwise, and in general, use ham or salt pork to season greens.
The technique of smothering greens can be used with many vegetables;
green beans work especially well. Meat is not necessary every day, don?t
be afraid to alter any dish to vegetarian tastes.

1 premature baby, born dead
Large bunch of mustard greens
2 white onions, 1 cup chopped celery
Vegetable oil (or hog fat)
Salt, pepper, garlic, etc.

Lightly brown onions, celery, garlic and meat in large heavy pot.
Add a little water and the greens (which should be thoroughly cleaned and washed).
Smother slowly for at least 2 hours, adding small amounts of water
when it starts to stick.
Stir frequently.
When ready - serve with rice, grilled smoked sausage, green salad, and iced tea.
Coffee and apple pie then brandy.

Maternity Ward Pot Luck Dinner

If you can?t get anything fresh from the hospital, nursery, or morgue;
you can at least get rid of all the leftovers in your refrigerator.

1 - 2 lbs. cubed meat (human flesh, chicken, turkey, beef...)
1 -2 lbs. coarsely chopped vegetables
(carrots, potatoes, turnips, cauliflower, cabbage...)
Bell pepper
onions
garlic
ginger
salt pepper, etc.
Olive oil
butter

Brown the meat and some chopped onions, peppers, and garilic in olive oil,
place in baking dish, layer with vegetables seasoning and butter.
Bake at 325&#65533; for 30 - 45 minutes.
Serve with hot dinner rolls, fruit salad and sparkling water.

B&#65533;b&#65533; Buffet 1

Show off with whole roasted children replete with apples in mouths -

cup shredded cabbage
1 cup bean sprouts
5 sprigs green onion, finely chopped
5 cloves minced garlic
4-6 ounces bamboo shoots
Sherry
chicken broth
oil for deep frying (1 gallon)
Salt
pepper
soy & teriyaki
minced ginger, etc.
1 tablespoon cornstarch dissolved in a little cold water
1 egg beaten

Make the stuffing:
Marinate the flesh in a mixture of soy and teriyaki sauces
then stir fry in hot oil for till brown - about 1 minute, remove.
Stir-fry the vegetables.
Put the meat back into the wok and adjust the seasoning.
De-glaze with sherry, cooking off the alcohol.
Add broth (optional) cook a few more minutes.
Add the cornstarch, cook a few minutes till thick,
then place the stuffing into a colander and cool;
2 hours
Wrap the rolls:
Place 3 tablespoons of stuffing in the wrap, roll tightly -
corner nearest you first, fold 2 side corners in,
wrap till remaining corner is left.
Brush with egg, seal, and allow to sit on the seal for
a few minutes.
Fry the rolls:
325&#65533; if using egg roll wraps, 350&#65533; for spring roll wraps.
Deep fry in peanut oil till crispy golden brown, drain on paper towels.

Lemon Neonate

Turkey serves just as well, and in fact even looks a bit like a
well-dressed baby. By the time you turn the child?s breast into

Pour stock over onions and drippings, carve the meat and
place the slices in the au jus.

Bisque ? l?Enfant

Honor the memory of Grandma with this dish by utilizing her good
silver soup tureen and her great grandchildren (crawfish, crab or
lobster will work just as well, however this dish is classically
made with crawfish).

Stuffed infant heads, stuffed crawfish heads, stuffed crab or lobster shells;
make patties if shell or head is not available
(such as with packaged crawfish, crab, or headless baby).
Flour
oil
onions
bell peppers
garlic salt, pepper, etc.
3 cups chicken stock
2 sticks butter
3 tablespoons oil

First stuff the heads, or make the patties (see index)
then fry or bake.
Set aside to drain on paper towels.
Make a roux with butter, oil and flour,
brown vegetables in the roux, then add chicken stock and
allow to simmer for 20 minutes.
Add the patties or stuffed heads, and some loose crawfish,
lobster, long piglet, or what have you.
Cook on low for 15 minutes, then allow it to set for at least
15 minutes more.
Serve over steamed rice; this dish is very impressive!

Stuffed Cabbage Rolls

Babies really can be found under a cabbage leaf -
or one can arrange for ground beef to be found there instead.

8 large

wanted to thank everyone for helping me out, and happy holidays

originally i wanted to use random wire:
My tuner can tune a random wire , it's what i'd prefer to use, but since
i gotta use a counterpoise i started to think a ctr feed dipole of
some kind would be 'best' for me, i got a balun and such and

taking all the advice, i realize that there is no garantee of no tvi,
i just wanted to take some steps that might not have been obv to me to
help minimize it and i believe i am in the ballpark

i doubt most hotels will 'enable' me to put wires up outside, the
flebag roadside ones with back windows into the woods might :)

otherwise i'll just see what a dipole brings me luck wise

i'd try a verticle, i have a ats100 but it's in a small room running
the counterpoise has always been a bit squirrelly

i seem not to always have 'luck w/a random feedback wise perhaps i am
doing something wrong my lengths are ok but birdies drop in now n
then

i made a reg dipole and a windom seems ok feedback wise and least tvi
based on my non scientific tests so far

based on the tips here guess i am where i need to be

thanks much appreciation and happy holidays

Well, you could always stick a TS-2000 rig in the car, and run "sky command" with a TH-D7a.

I run APRS in a similar manner, HT on flea power, talking through the car's transponder which I configure into a temporary digipeater. It's got a nice antenna, and 50W output, and a nice big battery. Makes life much easier.

As for telephone interference - its the phone's fault usually.
When you shop for a phone - pick it up and hit it on the side with the heel
of your hand - and if you hear a 'ding' (a bell) then it usually will be
ok - (will not receive your radio signals)
as for tv - it should be designed to take interference. sometimes high-pass
filter will help on the tv

## 4187. Newbie question: how many tuners can a single antannae attached to ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-26 06:17:31 UTC

I'm trying to find out if it is feasible to build a box that is
attached
to a single rooftop antannae but with multiple tuner cards/chips in it.
I'm trying to record multiple shows over-the-air(onto local disks)
simultaneously.

>I'm trying to record multiple shows over-the-air(onto local disks)
>simultaneously.

Sure. You'll want to have some sort of 75-ohm splitter, to divide the signal from the antenna and provide isolation between the tuners.

Depending on the strength of the incoming signal, the number of ways you wish to split it, and the sensitivity of the TV-tuner cards, you may need an RF amplifier (either at the antenna, or as part of the splitter).

How many simultanous recording operations you can do is going to depend on the tuner/compressor/capture cards, the PCI and disk bandwidth of your hardware, the sophisitication of your operating system and application, etc.

# 4190. AM aerial problem

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-26 08:15:50 UTC
From: David Flew <dgf3@labyrinth.net.au>
Message-ID: <cqls57$262b$1@arachne.labyrinth.net.au>
Source record: 84687

Hi
Can someone help me with a solution to my AM radio problem. I have just replaced a cheap clock radio with an expensive and much better sounding one. The aim was to improve sound quality ( which it has done) and reduce the interference from ADSL modem ( which it hasn't). This is a reasonably expensive clock radio, with no external AM aerial connection. Being used bedside, it needs to be oriented so that you can see the clock face. Of course Murphy's law prevails, and the ideal orientation for seeing the clock, dial etc is at almost exactly 90 degrees to the ideal orientation for best reception. In the "best reception" orientation the ADSL interference is minimal, and quite acceptable to the radio's owner.

Re-arranging the bedroom layout to suit the radio isn't an option, and the radio's owner really likes the AM programming. So I'm looking for another solution.

Is it possible to have some sort of external aerial ( I'll avoid even trying to spell the ant..... word correctly ), feeding via co-ax to a coil or perhaps ferrite rod, close to the clock radio? We are about 30 km from the main transmitter of interest, ( 774 Melbourne 50kW ) so signal strength outside house should not be a problem.

Suggestions welcome.

David

At the head of the list of those egregious ignoramuses (ignorami?) surely is the late Dr. John Kraus, W8JK, author of the textbook _Antennas_, surely the most respected and quoted textbook on the subject of all time.

I'm sure glad we have true scholars to correct us and show us the the error of our ways and the true path to enlightenment. It was truly awful to have been a victim of such ignorance for so long. Thank you Mr. Bean!

It is official; i just read in one of my electronigs mags i get that
the FAA indeed has ruled that airlines can allow use of computers over
the net when flying.
But it is up to each given airline to modify their own giudelines (as
they see fit).

"Faraday shield" to some degree is a myth.
I have seen radars inside quonset huts track a *bird* flying a few
miles away (thru the metal wall)!

You must have some strange buddies. Who in the world would set up a radar within a metal hut? And even if they did, who would think it's a good idea to stay inside with it if it were on?

There's nothing mythical about the Faraday shield; it works really well, so long as there are no discontinuities (apertures) and sufficient thickness and conductivity. Under real-world conditions, steel works pretty good, and any thickness sufficient to support itself will yield great shielding effectiveness. So the only real performance variable left is the holes in the conductive surface. How many, maximum dimension, proximity of radiating source to the shield, etc.

While I would expect a Quonset hut to really mess up the accuracy of a radar, it likely wouldn't be a good shield, as the floor isn't metal, I don't think the ends are metal, and the various skin panels are rather poorly RF bonded.

A bit of lateral thinking perhaps?

Why not either move your ADSL modem, or wrap it in cooking foil and
earth the foil?

I say it is worth the try.

The interference may not be directly from the DSL modem itself, but leaking from the cables. If I recall correctly, the DSL signal (at least here in the USA) is a couple of watts somewhere aorund the AM broadcast band. So you essentially have a 2 watt transmitter pumping out wide-band trash within a few meters of your receiver.

There used to be a 'AM signal booster' available. All it consisted of was a coil of wire about 8 inches in diameter witha variable capacitor for tuning. You just placed it next to your AM radio and the coil coupled into the built-in loopstick antenna.

---

Just to note that the net pattern of a real dipole near the ground is NOT its classic, free-space form to begin with, and could vary as it is rotated as a function of varying environmental effects.

It's probably more important to worry about the mins than the maxes, but no doubt you won't exactly know in which directions any of them exist, anyway.

You use weasel words like 'to some degree' to avoid talking about the
truth. Radio waves don't go thru a sheet of metal.

> I have seen radars inside quonset huts track a *bird* flying a few
> miles away (thru the metal wall)!

No, not thru a metal wall. I saw the radar go thru the wooden walls of
the bldg when I was in radar repair school in the army. But that was
wood. Your so-called metal quonset hut was probably wood or fiberglass.

If you saw anything, it was probably your own reflection off the metal walls, IF it didn't fry you like a porkchop in a microwave oven!

Hi all!

Please give me advice how can i connect external sw or mw antenna to
reciever that does not have connector for ext. antenna?
I opened reciever and see that there is ferite with one coil of copper
wire... but theare are four wires comeing from that "coil" to circuit board
of reciever (two coils one on top other?).....

i have randoom wire + 9:1 trafo + coaxial 50 ohms cable.... and i can use
combination with 300 oms twin lead cable....

thanx

Just don't get an amp that is meant to be used with cable. You need the kind
meant for off the air signals. Or, a single output amp with 10 - 15 db gain
followed by a 1:4 splitter.

Do a Google search on CCrane. They sell a couple of antennas that should help you out. One is the Select-A-Tenna. It is a loop such as Jim referred to. It works quite well. Improves reception dramatically and is directional with good nulls to kill the noise. The second mounts outside and runs into the radio via cable. There is a ferrite bar that attaches to the radio so no connection required.

Wind your own antenna primary on the loopstick.Just a few turns should provide enough coupling without upsetting the circuit. Twist the antenna primary coil leads and route them outside the radio for antenna and ground connections.

Best regards, Richard Harrison, KB5WZI

Hello,

Yes, easy... Modify it to obtain a Levy and add a Levy coupler.
Forget the direct coax feeding through a CB miracle-black-box. Use a longer ladder line right to the Levy coupler, the dipole should be long enough.

> Ed
> wb6wsn
>

I do not think your objections concerning the floor or the bonding of
the panels are too relevant.

The ends are metal and not relevant either.
The radar was pointing right at the wall (no windows nearby); any presumed leakage via remote holes that you assumed might allow the transmitted signal to leak, but would then not be focused on the bird(s) and the path lengths would vary.
But the reflected signal from the bird or birds would be rather weak and could not possibly be received via the same wild path(s) to a very directional antenna.

My point is that a Farady shield is a good attenuator, but not "perfect" as ASSuMEd.
And it sure is not "flat" in attenuation characteristic as a function of frequency.

Jim and others. I've played around with ADSL modem location, orientation etc, and whilst it's the cause of the noise, it's the low signal strength at the radio which is what I have to fix. If the radio is right next to ( inches) the modem, and is oriented optimally, the interference is minimal.

I'd hoped for a home grown rather than a commercial solution - but my AM aerial knowledge faded once I stopped playing with crystal sets and battery powered valve radios some decades ago. Also CCrane isn't well represented in the antipodes.

> And it sure is not "flat" in attenuation characteristic as a function
> of frequency.

Those weren't objections, they were speculations on my part as to how you boys could have been finessing the generally applicable laws of physics.

But truly, the story stinks. So you and your army buddies are in this metal hut, with a fairly high-power radar, and somebody comes up with the bright idea to turn the thing on. Apparently no thought about RF personnel hazards and no concern about strong reflections cooking your detector. Did you test your M16's in a Quonset hut too?

Next point. "The radar was pointing right at the wall..." Now tell me, in a semi-circular Quonset hut, how do you point anything "right at the wall"? Maybe straight up?

Now, a bird doesn't have a very big radar cross section, maybe only about 0.01 square meters, so the return loss is really big. And to resolve a single bird, I'm gonna guess that you had an X or K band radar. So let's run some numbers. Let's say you had a 100kW radar, with a 30 dBi antenna of 1 square meter aperture. At 1500 meters, your detector power would be about 1 picowatt, or -60 dBm. Well hey, that's pretty decent, I'll bet you could see a bird at one mile.

But that's assuming no loss at all due to the metal hut skin. Let's see what happens if we say that the metal hut walls give us only 40 dB of shielding (by absorption or reflection, it doesn't matter). That bites 80 dB out of your path budget, putting your detector signal down to -140 dBm. I think your story just ran out of luck.

Now you can argue about the 40 dB shielding effectiveness of the metal wall, but I'll say that I was being very generous about that. At 10 GHz, I know (How? Easy, I do it everyday. Just 3 days ago, I was keeping some 1.3 GHz from radiating off of some cables, and it was common old Reynolds Wrap to the rescue.), I can get >100 dB out of a sheet of aluminum foil. The SE is so damn high from the material that the only significant factor is when the energy finds a path around the shield.

Don't try to argue that a Faraday cage leaks; you appear to be trying to build a general case based on your experience of always having observed leaky structures. Sure, I know that shielding varies with lots of factors, conductivity, permeability, thickness, frequency, angle of incidence, distance from source, and then there's the problem of apertures. But your hut, with plain old galvanized steel about 1/16" thick, would make a great shielded enclosure, as long as the joints didn't leak.

BTW, I don't like using the term "Faraday cage". Despite all due respect to Mr. Faraday, calling it a shielded enclosure is a clearer description.

# 4223. TV antenna impedance measurements with MFJ-269.

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-27 14:09:32 UTC
From: pdrunen@aol.com
Message-ID: <20041227090932.11389.00002980@mb-m29.aol.com>
Source record: 84720

Hi Group,

Have a MFJ-269 here (new toy) and did a bit of expermienting with the TV antenna over the Christmast weekend, I have one of those 13 element antenna from radio shack, I don't know the exact part number.

I tied the MFJ-269 into the 300 ohm to 75 ohm balun at the antenna. The antenna being about 20 feet up on the house peak.

Looking at the impedances I got, nothing really looked good at the TV frequencies as I would have expected.

If the match is this bad, I would expect alot of loss from the fact that I run 75 ohm cable down from this antenna to the TV set.

Could my reading be mis-leading since the balum is a 4:1 going from 300 ohm to 75 ohm?

Has anyone done this before and posted the data? I would be interested to see.

I don't have my data in front of me at this time so I don't have any measurements to post.

I really find the MFJ-269 an exceptional device for the antenna experimenter.

Tnx de KJ4UO

A plane window, like the fuselage itself, acts as apipe below cutoff
frequency. Minimum size for low attenuation is 1/2-wavelength.

The thicker the window frame, the longer the waveguide and the greater
the attenuation at frequencies below cutoff. See page 277 of
"Transmission Lines, Antennas, and Wave Guides" by King, Mimno, and Wing
to quantify the attenuation. It`s big below cutoff.

Best regards, Richard Harrison, KB5WZI

Dear KJ4UO,
You might look through the user's guide and check me on this, but is it not the case that the MFJ-269 is designed and calibrated for 50 ohms? If that is the case, as I think it is, then anything other than 50 ohms is going to look like it has high SWR. If you TV antenna is what it is supposed to be, then looking into the 300 ohm Xfrm would look like 300 + j0 (ideally) and if you look into the 75 ohm cable, instead, it would look like 75 + j0 (ideally). The SWR in those two cases would be 6 and 1.5, respectively and that's the BEST you would get.

You will want to measure Z, not SWR. My offhand guess is that impedances
between 25 and 225 Ohms are about as good as you could expect. There will
probably be at least one frequency between channels2 & 6 and one between
channels 7 & 13 where you get some R + j0.

You might also want to put the MFJ in the mode where it displays parallel R
& X. It might show more of a trend.

The antenna not being 300 Ohms does not result in high SWR loss in the coax.
Your receiver not being 75/300 Ohms would. This is the inverse of the

transmitting case.

The 269 has an "Advanced 3" menu (page 30) that allows you to set the
SWR reference impedance to values other than 50 ohms, and measure
line loss and SWR in systems other than 50 ohms.

---

The important thing with a TV antenna is broadband response across each
6 MHz channel. Signal loss can be made up with an amplifier mounted at
the antenna, but if there is severe impedance variation across a
channel, you will have a lot of ghosting in the picture. Some
frequencies will have a high SWR and others not, and that will cause
differing amounts of reflection across the band.

This same problem exists with TV transmitting antennas, and engineers go
to great lengths to make the response uniform.

Hi Bill,

Actually, ghosting is path problem where two signals time lag
(reckoned by distance traveled by different paths - at least 100s of
meters if not km) present the viewer with two pictures.

The impedance variation gives rise to color distortion, smearing, due
to relative phase shift and/or BW clipping.

The "ghosting" I'm talking about is a very close-spaced ghost, perhaps
1/4 inch or less on the screen. It can definitely be caused by a poor
antenna. I used to install TV antennas for a living, trust me on that.

If you're talking about a ghost spaced several inches away on the
screen, then your statement above is correct.

Hi Bill,

For the benefit of others, let's put this into perspective. The time
it takes to scan one line across the face of a TV screen, is 50ï¿½S
which from my Radar days would have been 5 Radar-Miles. As this is
TV, instead that scan line is 10 Miles long (for RF traveling at 5ï¿½S
per mile). All this math is going to be about 5-10% off:

If we take the TV screen to be a modern size of 30" diagonal - call it
25" across, then a ghost offset by one inch has its origins in a
reflection (somewhere) that increases the path length by 0.4 mile.
This, of course, presumes that the ghost is displaced horizontally
within the same scan line, and not offset by one vertical trace which
would add 12+ miles plus that 0.4 mile. Where did the extra 2+ miles
come from? Retrace time.

On occasion of poor coax shielding from the cable TV provider, I would
get leakage from strong local TV transmissions that would have ghosts
with huge offsets not only in time, but also picture content. It
would easily compute to 100s of miles path difference, but the lag
time (timed by jump-cuts) proved it was the difference between the
network feed and cable feed time (upwards to a second or two).

So, when we return to this ï¿½" ghost, for this particular TV set, the
dimension is 0.04 mile or about 200 feet. Sounds like a ringing line.

Look up the FCC approval number (from the decal) on the FCC website.
Reportedly, this will tell you everything you might want to know (so
I've read). Maybe.
Obviously, it'll be one of the unlicensed frequencies like 433 MHz.

How does that fit with the state-of-the-art theory that standing-wave
energy doesn't travel end-to-end but instead sorta sloshes from side-
to-side between nodes?

The Jr. version it too short to use much below 7 mhz. with a SWR the
internal tuner will match. Double the length of the legs for about 100 feet
overall. Beter yet , extend it to about 130 feet overall. You probably
would do beter to hook the wires together and use it as a single feed wire
and hook the other side of the rig to a good ground.

My thanks to all for responses to my quetion. And my somewhat belated response to the comment (above): I guess I must be somewhat ambiguous in reference to the low noise of a loop. I have always heard that proper loop antennas had a lower noise characteristic than other open ended antennas. The type of noise in question, I don't know. I suspect at my locations I have a combination of man made and atmospheric noises being received at my presesnt dipole.

Since I intend to build a new antenna, and since I am now forced to consider the construction of a folded dipole in lieu of the more difficult to erect loop, that was the reason for my original question.

I have two nice 100'+ trees between which it would be quite easy to install a dipole..... whether it be folded or standard depends on the comments I receive from you guys on the low noise characteristic I am questioning.

Airy R. Bean wrote:
"Those who are ignorant about the English Language and its etymology, especially the Yanks and nerdy types, have introduced the erroneous plural, "Antennas"."

Many words are rooted in formerly used languages. Today`s languages are determined by common usage.

John D. Kraus, Ph.D., W8JK was one of the world`s foremost radio antenna authorities. On page one of his 1950 edition of "Antennas" his first sentence is:
"A radio antenna may be defined as the structure associated with the region of transition between a guided wave and a free-space wave, or vice versa." The footnote to this sentence defines "antenna" in its zoological sense.

Note the book`s title is "Antennas". Kraus notes that in England the usage makes no distinction and that both insect and radio antennas are "antennae" in the plural. In the U.S. it`s antennae for the insects and it`s antennas for radios.

Webster created a U.S. dictionary due to independent usage of the English Language in the U.S.. It is a continuation of U.S. rebellion just as was the switch from tea to coffee. Experimentation finds converts on both sides of the ocean.

If "Antennas" is good enough for Kraus, it is surely good enough for me.

Best regards, Richard Harrison, KB5WZI

delicacy.
The sandwich originated in New Orleans, where an abundance of abortion clinics
thrive and hot French bread is always available.

2 cleaned fetuses, head on
2 eggs
1 tablespoon yellow mustard
1 cup seasoned flour
oil enough for deep frying
1 loaf French bread
Lettuce
tomatoes
mayonnaise, etc.

Marinate the fetuses in the egg-mustard mixture.
Dredge thoroughly in flour.
Fry at 375° until crispy golden brown.
Remove and place on paper towels.

Holiday Youngster

One can easily adapt this recipe to ham, though as presented,
it violates no religious taboos against swine.

1 large toddler or small child, cleaned and de-headed
Kentucky Bourbon Sauce (see index)
1 large can pineapple slices
Whole cloves

Place him (or ham) or her in a large glass baking dish, buttocks up.
Tie with butcher string around and across so that he looks like
he?s crawling.
Glaze, then arrange pineapples and secure with cloves.
Bake uncovered in 350° oven till thermometer reaches 160°.

Cajun Babies

Just like crabs or crawfish, babies are boiled alive!
You don?t need silverware, the hot spicy meat comes off in your hands.

6 live babies
1 lb. smoked sausage
4 lemons
whole garlic
2 lb. new potatoes
4 ears corn
1 box salt

crab boil

Bring 3 gallons of water to a boil.
Add sausage, salt, crab boil, lemons and garlic.
Drop potatoes in, boil for 4 minutes.
Corn is added next, boil an additional 11 minutes.
Put the live babies into the boiling water and cover.
Boil till meat comes off easily with a fork.

Oven-Baked Baby-Back Ribs

Beef ribs or pork ribs can be used in this recipe,
and that is exactly what your dinner guests will assume!
An excellent way to expose the uninitiated to this highly misunderstood
yet succulent source of protein.

2 human baby rib racks
3 cups barbecue sauce or honey glaze (see index)
Salt
black pepper
white pepper
paprika

Remove the silverskin by loosening from the edges,

Ed. if you let the ends of the dipole be the high points and avoid the inverted-vee (skip the temptation for a little wider bandwidth of the vee, it comes at some expense of optimum dipole performance and low noise of a real dipole) you should be very happy with new antenna. I too use nearly 100' trees and achieve between 1/4~ and 1/2~ elevation for the 60-70 meter bandwidth. I stopped at that height only because it was a point at which the tree trunks exhibited very little movement. With a 125' span between them, that was important! Higher would be better, but probably not survive high winds either. 3/16" milspec dacron holds a balun (supported only from both ends), the antenna copper, and all 60-odd feet of RG-8X feedline under it with no problem. I use kevlar standing rigging to hold the blocks of the running rigging for this antenna. This allows more flexibility than if the main horizontal support line made a bight over each tree limb at its two ends. It has survived two hurricanes, many Nor'Easters and a lot of ice as well. Not too many locales have all those extremes ;-)

Tie with butcher string around and across so that he looks like
he?s crawling.
Glaze, then arrange pineapples and secure with cloves.
Bake uncovered in 350° oven till thermometer reaches 160°.

Cajun Babies

Just like crabs or crawfish, babies are boiled alive!
You don?t need silverware, the hot spicy meat comes off in your hands.

6 live babies
1 lb. smoked sausage
4 lemons
whole garlic
2 lb. new potatoes
4 ears corn
1 box salt
crab boil

Bring 3 gallons of water to a boil.
Add sausage, salt, crab boil, lemons and garlic.
Drop potatoes in, boil for 4 minutes.
Corn is added next, boil an additional 11 minutes.
Put the live babies into the boiling water and cover.
Boil till meat comes off easily with a fork.

Oven-Baked Baby-Back Ribs

Beef ribs or pork ribs can be used in this recipe,
and that is exactly what your dinner guests will assume!
An excellent way to expose the uninitiated to this highly misunderstood
yet succulent source of protein.

2 human baby rib racks
3 cups barbecue sauce or honey glaze (see index)
Salt
black pepper
white pepper
paprika

Remove the silverskin by loosening from the edges,
then stripping off.
Season generously, rubbing the mixture into the baby?s flesh.
Place 1 quart water in a baking pan, the meat on a wire rack.
Bake uncovered in 250° oven for 1° hours.

When browned, remove and glaze,
return to oven and bake 20 minutes more to form a glaze.
Cut ribs into individual pieces and serve with extra sauce.

Fresh Sausage

If it becomes necessary to hide the fact that you are eating
human babies, this is the perfect solution.
But if you are still paranoid, you can substitute pork butt.

5 lb. lean chuck roast
3 lb. prime baby butt
2 tablespoons each:
salt
black, white and cayenne peppers
celery salt
garlic powder
parsley flakes
brown sugar
1 teaspoon sage
2 onions
6 cloves garlic
b

perhaps)
1 inch cubes of tender meat, preferably from the nursery
Onions
bell peppers
Wooden or metal skewers

Marinate the meat overnight.
Get the grill good and hot while placing meat, vegetables, and
fruit such as pineapples or cherries on the skewers.
Don?t be afraid to use a variety of meats.
Grill to medium rare,
serve with garlic cous-cous and saut&#65533;ed asparagus.
Coffee and sherbet for desert then walnuts, cheese, and port.
Cigars for the gentlemen (and ladies if they so desire)!

Crock-Pot Crack Baby

When the quivering, hopelessly addicted crack baby succumbs to death,
get him immediately butchered and into the crock-pot, so that any
remaining toxins will not be fatal. But don?t cook it too long,
because like Blowfish, there is a perfect medium between the poisonous
and the stimulating. Though it may not have the same effect on your
guests, a whole chicken cooked in this fashion is also mighty tasty.

1 newborn - cocaine addicted, freshly expired, cleaned and butchered
Carrots

salt pepper, etc.
Olive oil
butter

Brown the meat and some chopped onions, peppers, and garilic in olive oil,
place in baking dish, layer with vegetables seasoning and butter.
Bake at 325° for 30 - 45 minutes.
Serve with hot dinner rolls, fruit salad and sparkling water.

B°b° Buffet 1

Show off with whole roasted children replete with apples in mouths -
and babies? heads stuffed with wild rice. Or keep it simple with a
hearty main course such as stew, lasagna, or meat loaf.

Some suggestions

Pre-mie pot pies, beef stew, leg of lamb, stuffed chicken, roast pork spiral ham,
Cranberry pineapple salad, sweet potatoes in butter, vegetable platter, tossed salad with
tomato and avocado, parsley new potatoes, spinich cucumber salad, fruit salad
Bran muffins, dinner rolls, soft breadsticks, rice pilaf, croissants
Apple cake with rum sauce, frosted banana nut bread sherbet, home made brownies
Iced tea, water, beer, bloody marys, lemonade, coffee

The guests select food, beverages, silverwar

# 4252. Re: AM radio reception inside passenger planes?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-28 05:23:35 UTC
From: Robert Baer <robertbaer@earthlink.net>
Message-ID: <26BCB513.4426CAFC@earthlink.net>
Source record: 84647
Cross-posted to: rec.travel.air,rec.radio.amateur.antenna,sci.electronics.equipment

8 large cabbage leaves
1 lb. lean ground newborn human filets, or ground chuck
Onions
peppers
celery
garlic
soy sauce
salt pepper, etc
Olive oil
breadcrumbs
Tomato Gravy (see index)

Boil the cabbage leaves for 2 minutes to soften.
In skillet, brown the meat in a little olive oil,
then add onions, peppers, and celery (all chopped finely)
and season well.
Place in a large bowl and cool.
Add seasoned breadcrumbs and a little of the tomato gravy,
enough to make the mixture pliable.
Divide the stuffing among the cabbage leaves then roll.
Place seam down in a baking pan.
Ladle tomato gravy on top,
and bake at 325&#65533; for 30 - 45 minutes.

Umbilical Cordon Bleu

Nothing is so beautiful as the bond between mother and child,
so why not consume it?
Children or chicken breasts will work wonderfully also.

4 whole umbilical chords (or baby breasts, or chicken breasts)
4 thin slices of smoked ham, and Gruyere cheese
Flour
eggwash (milk and eggs)
seasoned bread crumbs
1 onion
minced
salt
pepper
butter
olive oil

Pound the breasts flat (parboil first if using umbilical
cords so they won?t be tough).

Place a slice of ham and cheese on each, along with some minced onion
then fold in half, trimming neatly.
Dredge in flour, eggwash, then seasoned breadcrumbs;
allow to sit for a few minutes.
Saut&#65533; in butter and olive oil until golden brown,
about 6 minutes on each side.

Shish Kababes

As old as the hills, this technique has employed seafood, beef, pork, lamb, poultry, and vegetables; just about anything can be grilled, and young humans are no exception!

High quality marinade (Teriyaki and garlic perhaps)
1 inch cubes of tender meat, preferably from the nursery
Onions
bell peppers
Wooden or metal skewers

Marinate the meat overnight.
Get the grill good and hot while placing meat, veget

Free quick easy money Amazing !!!!!!!!!!!!
Date: 22 Dec 04

Comments

HOW TO TURN $6 INTO $6,000!!!!!! READING THIS COULD CHANGE YOUR LIFE!
I

found this on a bulletin board and decided to try it. A little while
back, I was

browsing through newsgroups, just like you are now, and came across an
article

similar to this that said you could make thousands of dollars within
weeks with

only an initial investment of $6.00! So I thought, Yeah right, this
must be a

scam,but like most of us, I was curious, so I kept reading. Anyway, it
said that

you send $1.00 to each of the 6 names and address stated in the
article. You then

place your own name and address in the bottom of the list at #6, and
post the

article in at least 200 newsgroups. (There are thousands) No catch,
that was it.

So after thinking it over, and talking to a few people first, I thought
about

trying it. I figured: what have I got to lose except 6 stamps and
$6.00, right?

Then I invested the measly $6.00. Well GUESS WHAT!!... within 7 days, I
started

getting money in the mail! I was shocked! I figured it would end soon,
but the

money just kept coming in. In my first week, I made about $25.00. By
the end of

the second week I had made a total of over $1,000.00! In the third week
I had

over $10,000.00 and it's still growing. This is now my fourth week and I have

made a total of just over $42,000.00 and it's still coming in rapidly. It's

certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!!

Let me tell you how this works and most importantly, why it works....Also, make

sure you print a copy of this article NOW, so you can get the information off of

it as you need it. I promise you that if you follow the directions exactly, that

you will start making more money than you thought possible by doing something so

easy! Suggestion: Read this entire message carefully! (print it out or download

it.) Follow the simple directions and watch the money come in! It's easy. It's

legal. And, your investment is only $6.00 (Plus postage) IMPORTANT: This is not a

rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it

really works!!!! If all of the following instructions are adhered to, you will

receive extraordinary dividends. PLEASE NOTE: Please follow these directions

EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains

successful because of the honesty and integrity of the participants. Please

continue its success by carefully adhering to the instructions. You will now

become part of the Mail Order business. In this business your product is not

solid and tangible, it's a service. You are in the business of developing Mailing

Lists. Many large corporations are happy to pay big bucks for quality lists.

However, the money made from the mailing lists is secondary to the income which

is made from people like you and me asking to be included in that list. Here are

the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the

following on each piece of paper;PLEASE PUT ME ON YOUR MAILING LIST. Now get 6 US

$1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will

not be seen through the envelope (to prevent thievery). Next, place one paper in

each of the 6 envelopes and seal them. You should now have 6 sealed envelopes,

each with a piece of paper stating the above phrase, your name and address, and a

$1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL!

You are requesting a legitimate service and you are paying for it! Like most of

us I was a little skeptical and a little worried about the legal aspects of it

all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they

confirmed that it is indeed legal! Mail the 6 envelopes to the following

addresses:

#1)Randall Hines 22 Stature Dr. Newark
DE 19713

#2) Mike Sharrer 921 West State St. Coopersburg PA 18036

#3) Jeffrey Hyun 17414Stark Ave Cerritos,CA 90703

#4) James Adair the third 22 Over Rd. Feasterville PA 19053

#5) TSR Solutions 15907 Golden Eye CT Parker CO 80134

#6) Daryl L. 6063 Roosevelt Blvd Apt# 216 Philadelphia PA 19149

STEP 2: Now take the #1 name off the list that you see above, move the other

names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the

list. STEP 3: Change anything you need to, but try to keep this article as close

to original as possible. Now, post your amended article to at least 200

newsgroups. (I think there are close to 24,000 groups) All you need is 200, but

remember, the more you post, the more money you make! This is perfectly legal! If

you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery

laws. Keep a copy of these steps for yourself and, whenever you need money, you

can use it again, and again. PLEASE REMEMBER that this program remains successful

because of the honesty and integrity of the participants and by their carefully

adhering to the directions. Look at it this way. If you are of integrity, the

program will continue and the money that so many others have received will come

your way. NOTE: You may want to retain every name and address sent to you, either

on a computer or hard copy and keep the notes people send you. This VERIFIES that

you are truly providing a service. (Also, it might be a good idea to wrap the $1

bill in dark paper to reduce the risk of mail theft.) So, as each post is

downloaded and the directions carefully followed, six members will be reimbursed

for their participation as a List Developer with one dollar each. Your name will

move up the list geometrically so that when your name reaches the #1 position you

will be receiving thousands of dollars in CASH!!! What an opportunity for only

$6.00 ($1.00 for each of the first six people listed above) Send it now, add your

own name to the list and you're in business! ---DIRECTIONS ----- FOR HOW TO POST

TO NEWSGROUPS---------- Step 1) You do not need to re-type this entire letter

to do your own posting. Simply put your cursor at the beginning of this letter

and drag your cursor to the bottom of this document, and select 'copy' from the

edit menu. This will copy the entire letter into the computer's memory. Step 2)

Open a blank 'notepad' file and place your cursor at the top of the blank page.

>From the 'edit' menu select 'paste'. This will paste a copy of the letter into

notepad so that you can add your name to the list. Step 3) Save your new notepad

file as a .txt file. If you want to do your postings in different settings,

you'll always have this file to go back to. Step 4) Use Netscape or Internet

explorer and try searching for various newsgroups (on-line forums, message

boards, chat sites, discussions.) Step 5) Visit these message boards and post

this article as a new message by highlighting the text of this letter and

selecting paste from the edit menu. Fill in the Subject, this will be the header

that everyone sees as they scroll through the list of postings in a particular

group, click the post message button. You're done with your first one!

Congratulations...THAT'S IT! All you have to do is jump to different newsgroups

and post away, after you get the hang of it, it will take about 30 seconds for

each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU

WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's it! You will begin

receiving money from around the world within days! You may eventually want to

rent a P.O.Box due to the large amount of mail you will receive. If you wish to

stay anonymous, you can invent a name to use, as long as the postman will deliver

it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.** Now the WHY part: Out of

200 postings, say I receive only 5 replies (a very low example). So then I made

$5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent

me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5

persons respond to each of the original 5, that is another $25.00 for me, now

those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each,

I will bring in an additional $125.00! Now, those 125 persons turn around and

post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will

make an additional $626.00! OK, now here is the fun part, each of those 625

persons post a MINIMUM 200 letters with my name at #2 and they each only receive

5 replies, that just made me $3,125.00!!! Those 3,125 persons will all deliver

this message to 200 newsgroups with my name at #1 and if still 5 persons per 200

newsgroups react I will receive $15,625,00! With an original investment of only

$6.00! AMAZING! When your name is no longer on the list, you just take the latest

posting in the newsgroups, and send out another $6.00 to names on the list,

putting your name at number 6 again. And start posting again. The thing to

remember is: do you realize that thousands of people all over the world are

joining the internet and reading these articles everyday?, JUST LIKE YOU are

now!! So, can you afford $6.00 and see if it really works?? I think so... People

have said, &quote;what if the plan is played out and no one sends you the money?

So what! What are the chances of that happening when there are tons of new honest

users and new honest people who are joining the internet and newsgroups everyday

and are willing to give it a try? Estimates are at 20,000 to 50,000 new users,

every day, with thousands of those joining the actual internet. Remember: play

FAIRLY and HONESTLY and this will really work.

# 4255. G5RV Too Short for 80 Meters ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-28 07:36:11 UTC
From: Gary
Message-ID: <5q22t09hgsse4mmghq5m0vmmvt62lmb6hi@4ax.com>
Source record: 84651

I've looked at some commercial "full size" G5RV's and the leg lengths are about 51 feet long each, that seems a tad short for 80 meters. Would I experience quite a bit of loss in the tuner ( External ) Or maybe I should try and erect a dipole with leg lengths as long as I can and feed it with 450 Ohm Ladder line or 300 Ohm twinlead and be able to operate on 30 meters ? I understand the G5RV doesn't work too well for 30 meters, and I need some place to operate during contests. My primary bands of interests are 80 thru 20 CW.

Thanks in advance.

Gary K8IQ

I was not alluding to leakage; a more accurate term would be
re-radiation.
Take an ordinary transformer; it radiates a magnetic field, despite
the fact that the core is a closed loop.
In fact, one could get nasty and say the same thing about a toroid
transformer.
Now add a shorted copper turn around the outside of the ordinary
transformer's core (i have seen this on many TV power transformers and
others as well).
What happens? That magnetic field induces a current in that shorted
turn, making an opposing magnetic field - thereby reducing the net
radiated magnetic field greatly - but not to zero.
Now, instead of using that closely wrapped copper shoted turn, put
that transformer inside that shielded room you love.
Results: great reduction, but not to zero.
Increase the frequency to something one might consider RF.
Now one has an RF transmitter inside that shielded room, inducing
currents in the wall(s).
Those currents create opposing fields, and greatly attenuate the

signal outside the walls.
But they are not zero.
BW, radar is usually pulsed, and in the megawatt to multi-megawatt region for the pulse.
Also, the quonset huts i saw had relatively vertical walls; the rounded curvature was more so near the top.
And it might help to ask the bird(s); they even dislike those pesky jets getting in their way.

You came up with this a few days ago, but did not,
or could not, substantiate your claim.

The word, "Antena" appears in modern Greek, and arrived
there in response to its widespread adoption by the World
to describe radio antennae.

It does not appear either as "Antena" or as "Antenna" in ancient
Greek dictionaries, at least in those that I can find on the Internet.

FAR more likely that the antenna for the radar was outside the hut.
There may have been one slaved to it, inactive, inside the hut to
demonstrate what's going on upstairs.

There are plenty of good reasons why such a demo wouldn't work as described,
from killing the detector with strong reflections, to massive
re-re-reflections inside the building, to the fact that radar relies on a
"pencil" beam that wouldn't survive through those walls in any rational way,
and so on.

My shielded enclosure only asks that I respect it; I don't think it would
provide better SE even if I told it that I loved it.

> Results: great reduction, but not to zero.

Nothing ever goes to zero; I'll usually settle for "great" reductions.

> Increase the frequency to something one might consider RF.
> Now one has an RF transmitter inside that shielded room, inducing
> currents in the wall(s).
> Those currents create opposing fields, and greatly attenuate the
> signal outside the walls.

You're getting a little fuzzy here. The propagating wave induces surface currents on the metal barrier. The currents "sink" into the metal, decreasing to about 37% (1/e) in what's called a "skin depth". At 10 GHz, a "skin depth" in steel is really thin. After even 10 skin depths, the current is down to only about 1/100,000 of what was on the surface. And there's a whole lot of more skin depths to go before the current is presented to the far surface of the steel barrier. And only then does the surface current on the far side of the barrier get to launch a propagating wave.

Note that the "opposing fields" you mentioned are on the INSIDE, the near surface, of the barrier. The reflected field is 180 degrees out of phase with the incident field, so, real close to the metal surface, the E-field nulls. OTOH, that reflected wave now goes marching back at you, creating lots of fun with out-of-phase energy pumped back into the original radiating element. Everybody sees bad, bad VSWR. And, since you guys were inside a metal hut, there's even more fun in store for you. Not all that energy goes back into the originating antenna. A lot of it just keeps bouncing around inside the hut, creating 3-D variations in power density. Think of yourself as a potato, slowly cooking.

So, to keep this straight, the current that survives Ohmic losses to make it to the far side of the barrier doesn't "greatly attenuate the signal outside the walls". It actually creates the signal (the propagating wave) on the far side of the barrier.

We can talk about aperture leakage and re-radiation from barrier impedance discontinuities some other time.

> But they are not zero.
> BW, radar is usually pulsed, and in the megawatt to multi-megawatt
> region for the pulse.

Multi-megawatt? Hmm, 10 MW? OK, and maybe a duty cycle of 0.01%? Isn't that 1 kW average? I own a 250 kW X-band radar that will do up to 0.1% duty cycle. I sure wouldn't sit in a metal box with that thing running! I wouldn't even want to be in the boresight of the antenna within a few hundred feet. I was trying to be charitable in assuming that nobody would be so dumb as to fire up a multi-megawatt radar INSIDE a metal hut. Looks like you guys proved me wrong!

Dear Gary,

When G5RV designed that antenna, it was designed for 20 meters.
What does that tell you?

Your own suggestion is a pretty good one. However, don't expect that
you will be lucky enough to have it tune to 1:1 on all frequencies,
just because you use a balanced feedline and a tuner. Usually, some
matching is necessary with discrete elements or transmission line
segments, stubs, etc.

If you want to take advantage of the extensive work of others on the
"all purpose" center fed dipoles, take a look at Cecil's web site.

That's because the "missing" portions are in the open wire section.
It still works at 80m and can be fed with 75ohm coax at the lower end
of the line via a 1:1 balun. Better still would be to bring the open
wire section into the shack and to an ATU.

From what I remember from using one of these many, many years ago, I
used 29ft 6 inches of 300 ribbon feeder as against 32 - 33 ft of open
wire (300 ohm ribbon has different velocity factor to the open wire
and 450 ohm ladderline)

>Would I experience quite a bit of loss in the tuner ( External ) Or
>maybe I should try and erect a dipole with leg lengths as long as I
>can and feed it with 450 Ohm Ladder line or 300 Ohm twinlead and be
>able to operate on 30 meters ?

Yes ... and use the 450 ohm ladder line

>I understand the G5RV doesn't work too
>well for 30 meters,

It was never designed for that band as we didn' have that allocation
when Louis, G5RV, introduced the antenna. That's why it's best to use
open wire right down to the shack. You can then use it on all of
todays HF bands via an ATU. The 102 foot "top" is also no magic then.
Make the legs as long as you can .... you might even be able to work
160 metres if you can get out enough wire!

BTW, please dont buy a G5RV !!! They are so easy to make and work out
cheaper. You also have the satisfaction that you made it yourself,
which is what amateur radio is (hopefully largely) about.

Have you considered putting up a 50 ohm coax fed inverted V 80 metre
dipole and then adding a 40 metre dipole to the same coax feed point?
It can come down at a sharper angle than the 80m one or run at right
angles to it. You'll then have 80, 40 and 15 metres since the 40m
dipole will work has 3 half waves in phase on 15. You can hang dipoles
for the other bands to the same feeder as well. Be prepared for some
cut 'n try of course! This system elimates the need for an ATU but
you'll find the usable bandwidth on 80m to be only just a couple of
dozen kHz or so. The open wire version will be tuneable across the
whole of each band via the ATU.

Good luck,

Peter, G3PHO

That's just a side-effect of the message having been posted to a 'test'
newsgroup - basically irrelevant to the real issue.

Look up 'hipcrime' in google for more info about what went on with the baby
recipes.

can't find a way to the obvious material.

It's very simple, no more than a dozen miles north of you. All of
maybe three turns to make to get on the road, and get off it at the
obvious source. You could have walked it by now. Using the Internet
as a research tool is all fine and well, but it hardly constitutes the
final say. Others could accomplish this I suppose, especially when
I've offered the author of the translation and the period.

Finding it on the net is neither difficult nor impossible, I just have
it simpler with a good library and the OED not 6 feet away. Not only
is it faster (consider how much time it has taken you to NOT
accomplish anything), but it would eventually be the reference used by
any link offered. ;-)

Or - you can wait until Google does it for you (news item, American
company is going to digitize the college libraries for the Brits).

The term Faraday screen, sield, or cage, has been applied to perforated continuous sheets of metal in this thread. That`s generally wrong.

A Faraday screen, shield, or cage is a network of parallel wires or strips connected together at one end but disconnected from each other at their opposite ends. I`ve worked at several broadcast stations which used Faraday screens at every tower to magnetically couple the tower to the feedline while eliminating all capacitive coupling. The purpose is to disadvantage harmonic coupling to the tower in which capacitance favors due to lowered capacitive reactance at the harmonic frequencies.

At the stations, two coupled coils are used. They are close together and share the same axis. Between the two coil forms is erected a heavy plate sliced with parallel cuts. These start at one edge of the plate but end before reaching quite to the other edge. The purpose is to eliminate capacitive coupling between the coils but to allow tight magnetic coupling between the coils. In the broadcast station they also have another salutary effect. The tower`s lightning strikes nearly all are terminated on the Faraday screen and kept out of the radio equipment.

A Faraday screen, shield, or cage is a network of parallel wires or strips connected on one end but disconnected from each other at their opposite ends. It`s similar to a conductive comb. The connected ends of the wires are usually grounded.

The open-circuit wires prohibit circulating current from wire to wire. Fields of the induced current would cancel the field of the inducing current thus canceling inductive coupling. Due to the gaps, the screen is transparent to the magnetic field but the wires capture the electrostatic lines of force and eliminate capacitive coupling through the screen.

A screen properly grounded at both ends of the wires sliminates magnstic and electrostatic coupling. It is a shield but not a Faraday shield. A continuous conducting shield is not a Faraday shield, even if perforated with small holes. A lot of screened rooms have been constructed from copper window screen. It decouples the contentents of the room from the whole world when done correctly.

Best regards, Richard Harrison, KB5WZI

Why the G5RV works well on 75m is explained using a Smith Chart on my
web page at: http://www.qsl.net/w5dxp/G5RV.HTM where it can be seen
that the series twinlead matching section transforms the antenna
feedpoint impedance of 36-j324 ohms to a resonant impedance of 17 ohms.
Even better is to install a 1000 pf cap across the line at the coax to
twinlead junction to achieve a near perfect match on 75m (remove for
use on the higher bands).

The special comb-like structure that Richard describes, which is deliberately constructed to block electric fields but transmit magnetic fields, is normally called a Faraday "screen" - but not a cage.

The term Faraday "cage" is reserved for a complete conducting enclosure that blocks both electric and magnetic fields from entering the interior.

The rest of the discussion is about how well an incomplete or penetrated enclosure might work as a Faraday cage.

Roy, W7EL wrote:
"The response of electrically large (on the order of a half wavelength and larger) dipoles and loops to electric and magnetic fields depends on the direction and distance to the source."

Yes. The dierectional response of a 1/2-wave folded dipole is the same as that of a 1/2-wave open-circuit dipole. The main difference may be the difference in impedance presented to the transmission line.

Here is my experience. Lightning is an extremely large noise. My corporation used VHF radios to interrogate remote data stations. For decades we used Andrew Corporation folded 1/4-wave unipoles atop high towers around the world in base stations to communicate with mobiles in any direction. These had proved indestructable. Both the stainless steel antenna and the radio used, with no lightning protection on the feedline, other than the Heliax used to connect the antenna with the radio. This was before we started the data radio operation. The Heliax is a common-mode rejecter due to its equivalent circuit.

For the data radios, the operation was point-to-point. Directional antennas were useful in this service. The data radios immediately started to be destroyed by lightning strikes. Problem was the yagi antenna. The driven element was an open circuit. We quickly fixed that with an short-circuit 1/4-wave stub shunted across the antenna at its feedpoint. No more lightning damage. The short-circuit removed enough of the off-frequency noise (lightning) to save the radios. So the operation continues decades later with Motorola transistorized mobile radios as the data base and remote stations.

Best regards, Richard Harrison, KB5WZI

Should be wider than that...I usually get 200-250-300 kc "2:1 SWR" on
80m,
using common fed dipoles. About the same as a single dipole...I just
checked
mine out of curiosity, and I'm tuned at about 3910kc. Using the SWR
meter
in the rig, I hit 2:1 at about 3.810. Actually, I usually tune about
3850 or
so, but it seems to have changed a bit, probably cuz a large tree was
cut down,
and I had to change the antenna layout a bit. But anyway, I'm getting
3.810
to 4.000 usable with no tuner if you consider 2:1 the limit. I am using
an
MFJ 989c tuner, but usually only for the wattmeter...But I can use it
to go
off the beaten path.. Right now, I've got 160,80,40 on one coax feed. I
can
use the tuner for any of the other bands. Even with the coax loss, it
usually
works ok about anywhere. Works real well on 30m, even though the SWR is
about
5:1 or so..At that freq, and the rg-213 I use, 5:1 doesn't add too
awful much
loss. I get real good reports. Running the different dipoles at right
angles
is the best, with almost zero interaction. As they start to parallel,
the
coupling between them will increase, but is usually no big deal.

It's best to always start, and tune the lowest band first, and then add
and
tune each higher band dipole as you go along. Thats the fastest and
easiest
way. If you have coupling problems, it will almost always show up on
the
higher band dipole. Almost never on the lower. IE: An 80 and 40 dipole
on
the same feed, would usually show any coupling/tuning problems on 40m.
Often,
just moving one of the 40 legs a few feet farther away will let it tune
fairly
normally. Once set up, and tuned, the performance of the paralleled
dipoles
will usually outdo most tuner driven/ladder line fed single dipoles. No
tuner losses, no knob fiddling, and you have a normal dipole pattern on
each
of the bands used. It's been my preferred setup for years as far as my
"everyday" lower band antennas. The efficiency is in the 95%+- range
depending
on the band..."I use 213 coax" Can't really improve on that much..Even
lowly
rg-58 will be pretty low loss on the lower bands, as long as the length
is
not excessive. MK

> Ed K7AAT

Myself, I would just build the standard dipole. As far as any far field

noise, I consider the two types the same in performance. The main
difference being the impedance step up on the folded version. As
Richard
mentioned, there may be lightning advantages to the folded version, but
for general HF noise, I don't think it would matter. You have to
consider
what noise is. It's RF. Your antenna is *supposed* to be able to
receive
noise. If it doesn't , it's defective as far as I'm concerned. Many
build
antennas that they claim to be low, or lower noise, but myself, I'm of
the
opinion they are usually building lower efficiency antennas which
naturally pick up less noise. To decrease the pickup of far field
noise,
you can change polarization, directional pattern, or efficiency. Being
as
your proposed dipoles will have the same polarization, and pattern, the
only thing left to reduce noise pickup is efficiency. Do you *really*
want to lose efficiency in order to reduce far field noise pickup? I
sure wouldn't...There may be an advantage as far as static buildup with
the folded dipole, but do you
actually have a static buildup problem? I don't have that problem here
in Houston. It's hardly ever dry enough around here.. Any common mode
noise problems are dealt with using baluns, chokes, etc...
To make the best decision, you need to know what noise? you are trying
to cut.
If it's general far field noise, you are chasing a dream that doesn't
really exist, unless you want to degrade your antenna system, or make
it directional, etc. I *want* my antennas to pick up noise, if it's
there to be picked up.

Lets me know they are working...:/ MK

Was it not an Ice Bucket which Faraday used to demonstrate the fact that the electrostatic charges repelled each other as far as possible, and therefore stayed on the outside of the bucket? The inside was electrically dead.
Ian.

# 4283. Re: Loop vx Folded Dipole noise factor

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-28 22:17:32 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <10t3ms32jumod99@corp.supernews.com>
Source record: 84580

There are three common sources of HF noise:

1. (Propagated) atmospheric noise. There's no magic antenna that can tell the difference between atmospheric noise and signals coming from the same direction as the noise. An antenna that attenuates one will attenuate the other by an equal amount. A directional antenna will improve the signal to atmospheric noise ratio only if the two are coming from different directions and the antenna can be oriented to favor the signal and reject the noise.

2. Static discharge. Rain and snow can carry static charges, creating noise at the antenna itself. Also, a gathering storm can cause a large static potential to build up on an ungrounded antenna, even to the point of corona at the antenna ends and arcing across the feedpoint. I saw this many times in Denver, but never here in western Oregon. This can be prevented by making a DC short or near short across the feedline with a resistor, RF choke, or shorted stub, or by using an antenna that inherently has a DC short across the feedpoint, and by avoiding any sharp points like wire ends. A loop of any size has both these features, although there are other ways to get them.

3. Local noise. One antenna can be much better or worse than another at rejecting noise that originates close to the antenna. Often, horizontal polarization is better than vertical for rejecting local noise, or any noise that's within surface wave range. If the noise source is very close -- within a fraction of a wavelength -- a small loop might help, since it's relatively insensitive to electric fields from sources which are very close by. However, it's difficult to make a small loop that's efficient, so it's usually a better choice for receiving, with some other antenna being used for transmitting.

For esthetic / XYL / neighboor reasons, I'm thinking of running balanced "ladder" line to the back of my yard, via 1" PVC pipe with appropriate measures to keep the water out, and burying it maybe a foot underground. Length of the run might be 20 feet along the bottom of a deck and then 60 feet buried, give or take. Then straight up a tree centered between two other trees to feed about a 80' center fed dipole.
Nothing else will be in the pipe with the feed line. Anyone have any thoughts on why this might or might not work? The ground where it could be buried, is on the moist side most of the year.

Hi Ian,

Maybe it was part of an office party. Anyway, Gauss demonstrated that electric charge FIELD LINES prefer as much separation as possible (which conforms to your charges being repelled). With a curvature, the field line normal to the surface will either cause line crowding or line spreading depending upon the geometry. With a positive curvature (the outside of a conducting shell) the lines spread; with a negative curvature (the inside of a conducting shell) the lines converge. Given that the bucket is conductive inside and out, he demonstrated that line proximity within the bucket drove the charges outside. This is not quite an issue of charges being repelled as far as possible, or they would be uniformly distributed inside and out.

By the same logic (and experience), charge will accumulate on the surface at the smallest radius - hence the points on lightning rods. By extension, this is also the source of capacitor failure at either the edges (smallest radius of a plate) or in surface burrs.

HCJB, in Quito, suffered from corona discharge and converted to loops (misnomer, actually box), they still suffered when the corners (smallest radius) supported the same discharge (being corner fed). They shifted to a center feed point and put the hi voltage nodes at the middle of a wire span.

I have a ground rod that has become corroded. My VOM measures no continuity between the rod and the ground wire.

Is there and easy spray-on cleaner of some kind that would make the ground rod shiney and conductive again, where I attach the ground wire? (I don't think I can pull the rod out to replace it; it'd be easier to fix what I have.)

Tnx,

Bob

> kb8tl

The wires in the ladder line would be much too close to the surrounding ground. You don't want anything within several times the wire spacing distance of either ladder line conductor except good quality insulators. (I don't know how good even the PVC might be but I suspect it would be good enough.)

If you could put the 1" PVC pipe inside some larger diameter PVC pipe, keep them concentric, and keep the water out of the space between them as well as the inside of the 1" PVC pipe, that might be OK since it would keep the ground farther away from the wires. The larger the diameter of the outer pipe, the better.

1" diameter pipe would require ladder line with very close spacing between the wires, in order to fit inside the pipe. Close spacing means low surge impedance, unless the wire diameter is small. All other things being equal, higher surge impedance lines with wider spacing have lower losses than lower surge impedance lines. Using smaller wire diameter in an attempt to get higher surge impedance in a closely spaced line is *not* the route to lower losses. So you may want to re-think the 1" diameter choice. But if you made the inside pipe diameter (and ladder line spacing) larger, you'd have to make the diameter of the outer pipe larger too.

Coax, provided you keep RF off of its outer surface, sounds like a simpler way to make the surrounding ground irrelevant.

Again scraping the very bottom of the memory banks, I seem to recall
that when lightning rods were first used (in the late 1700s), the
British used sharp points. The French, in the spirit of one-upmanship,
decided that theirs should have brass balls. DOH!!!

You can adjust the length of the feed line. But it is a trade-off. It takes a lot of experimentation to get a length that works ok for all frequencies of operation. The high SWR on the feed line produces different impedances at different frequencies and the length is a critical variable.

Very interesting! However the American Benjamin Franklin's pointed lightning rods (it was not a British design) was never scientifically challenged until a couple of years ago. Scientists have now shown that blunt-tipped air terminals are attached by lightning with significantly higher frequency than sharp tipped rods are. Pretty amazing that it took over 230 years to "discover" this! So scrap the concept that a sharp edge attracts charges, at least it does not attract lighting, the ultimate charge.

Odd thing to use, but it works: Worcestershire Sauce.
Easy to find at the groceries. I've used it on copper pennies for years, and
old copper wire. But if you solder the wire after cleaning, it smells like
you are cooking something, but solders just fine.

Most of the ground rods I've seen are steel, with a thin copper plating. If your rod has corroded enough that you've lost continuity with the ground wire, I'd guess that your rod's copper plating is probably gone or is badly degraded. This has two implications:

- You may not be able to clean it enough to re-establish a good contact

- The copper may be gone from the portion of the rod which is beneath the soil surface, and hence your ground conductivity may be shot.

The best fix would be to pull out the existing rod (I know, it's a pain... using some sort of hoist or jack might be the best way to get it out), hammer in a new one, and then use a NEC-approved corrosion-proof way of bonding the grounding wire to the new rod (this usually means welding it, I believe).

Did a Google on cleaning copper, and the most common cleaner for
copper pots appears to be vinegar and salt, or lemon juice and salt.
Maybe Worcestershire sauce has same ingredients?

Or, maybe I'll just have to drive a new ground rod :-)

The magic 8-ball known as Google seems to agree that you're right.
Most of the Worcestershire sauce recipies contain anchovies (quite
salty), and either vinegar or lemon or orange juice or some
combination thereof.

As to copper cleaners - one I remember favorably from my boyhood
puttering-with-chemistry days is a mix of sodium bicarbonate (baking
soda) and dilute ammonium hydroxide ("5% household ammonia water",
either clear or sudzy). The resulting slurry takes tarnish off of
copper or silver almost instantly (although I don't know how much of
the metal in the tarnish is returned to the surface and how much ends
up in the slurry).

Use with appropriate caution, gloves, and ventilation, of course.

Surely the ground conductivity doesn't depend on that thin plating of copper, does it? Isn't the conductivity of rust better than the dirt it's in contact with?

Why bother to try to clean? As mentioned, the copper has probably dissappeared from the ground rod, under ground. A trick you might try: Check your local garden center for Powdered Copper Sulfate (CU S O-4 )-it is used as a pest control, for gardens- also, is used as an ingrediant in the solution for plateing copper to items! (a greenish powder) Mix this with water, and
then pour it on to the ground rod/earth (warning- you may stearlize the ground - don't try this around ornimental plants, nor growth that you wish to keep alive!) May take several gallons, but with electrolyisis, may help replate the ground rod, and will certainly improve the ground's conductivity to the ground rod! As info, Jim NN7K

>it's in contact with?

The conductivity of the rod itself will certainly decrease by some amount, if when the copper is gone. I don't have a quantitative figure for this. Whether the rust (from the corroded steel) is more or less conductive than the soil surrounding it will probably depend to some extent on the soil conditions... but both will surely be less conductive than uncorroded metal (be it steel or copper). Every extra ohm in the current pathway is going to result in an increase in voltage rise across the grounding system if/when the system takes a hit.

From what I see (based on a quick skim of the DoD-issued MIL-HDBK-419A on grounding and lightning protection), the copper plating serves two important purposes: compatibility with the copper wire, and protecting the steel of the rod from corrosion. By itself, it doesn't seem to be critical for carrying the current.

If the copper's gone, and the steel is in direct contact with the soil, I'd be concerned about the rod suffering some fairly serious corrosion over a period of a few years. You might end up with a ground rod which was, in effect, only a foot or so long... it could break or be badly narrowed by corrosion not far below where it's hammered into the ground. This might seriously compromise its ability to shunt the charge of a lightning strike into the soil and keep the voltage rise on the attached wires to a level that minimizes damage.

It probably depends a lot on the soil chemistry... e.g. acidic soils would probably be harder on an unplated ground rod that more alkaline soils, and would degrade it more rapidly.

Additional followup: a technical report on ground-rod lifetime at
http://www.erico.com/public/library/fep/strike/LT0540.pdf has some
interesting conclusions.

It cites a study or two which suggests that ground rods with a 10 mil
copper coating should be good for a service life of up to 40 years.
With a 13 mil coating, 50 years.

Galvanized ground rods with a 3.9 mil zinc coating don't seem to be
good for more than a 10-year service life. One sample dug up after 10
years was corroded through, almost to the point of breaking, not far
below the soil surface.

Yessir my friend, the latter is your best move, and at about $12 it just isn't worth the worry about longevity of a compromised electrode! Do resist the temptation to push a new one back in the same hole, o.k.? ;-)

While you're at Home Depot, pick up a few, and add those extra ones you were meaning to do. It might be Lowe's that carries the pre-cut 25' lengths of #4 copper grounding wire for about $8. These are such cheap solutions to sleepless nights during thunderstorms!

My main problem is there is solid rock/limestone about a foot down. I
can't even penetrate it with my Glen Martin ground rod driver. So
putting down a new rod probably means digging a shallow ditch and
laying it down horizontally -- or laying some radial wire, or both.

There is more to the Franklin rods used in England: George III is said to have required the ends to be converted to round from pointed when the Revolution started - a pointed slam at Dr. Franklin. Nevertheless, the houses (once there were two) of parliament were protected by Dr. Franklin's rods.

It would have been so easy for the English to have co-opted Dr. Franklin and quite changed the course of history. Instead, he conned the French out of the critical support needed to win our freedom. 73 Mac N8TT

This may be an interesting experiment - and I for one will appreciate a
report of your success.
I would suggest trying it without burying it first - If it works
above-grade, it may work buried.
The biggest challenge will be keeping water out of the pipe.

Jack,

All three references are of the same article. Note the rebuttals at
the end of one of them.

I would also find it hard to believe that ANY rods on a 12000 foot
mountain were not hit in 7 years!

That study would suggest that pointed rods were excellent lightning repellers and would protect things from being struck. Exactly what Franklin first thought.

If not excellent repellers then it would be highly suspect of the placement of the pointed rods on the mountain.

Bob:

If I had to do what you are proposing, and could find no alternative, I would go purchase a bunch of the foam pipe insulation, experimentally determine what spacing 6" chunks of it would still support the line adequately centered in the pipe, and put that in 1-&#65533;" or 1-&#65533;" pipe, whichever it fit the best. Bigger is better as someone else pointed out. You might want to test some for RF loss, as the black version may well contain carbon. Styrofoam would be the best choice, but I don't know of a cylindrical form of Polystyrene foam. Maybe 1" strips of it cut from 4' X 8' sheets of 1" foam would work. Use your imagination, for gosh sakes. The PVC will survive underground satisfactorily, but paint the exposed ends for longest life (or use short pieces of gray conduit for the exposed portion).

Bob, KB8TL wrote:
"Anyone have any thoughts on why this might not work?"

I`ve worked in several medium wave broadcast stations which used buried coax to feed the towers. No problems..

I worked in a shortwave broadcast plant where we needed a 100 KW dummy load. So we constructed a parallel wire 600-ohm line only about 2 feet above the earth using Copperweld wires a few hundred feet long. It could boil the dew on the groud and bring earth worms to the surface. It also did a great job of dissipating the 100 KW.

Anytime parallel line such as twinlead or ladderline approaches ordinary earth, loss soars. Direct burial is impractical even inside fairly large conduit. Use one or two lengths of waterproof coax as buried line.

Best regards, Richard Harrison, KB5WZI

Just recently installed a Hustler 4-BTV ground mounted vertical. I added 20 tuned radials on 10,15,and 20M each for a total of 60 tuned radials. I also added 12 tuned radials on 40M. I was lazy and bought them from DX Engineering where I also got their stainless steel ground radial plate and the nifty tilt-over mount for the 4-BTV (and other verts as well). I did a little tweaking on the 4-BTV today and the tilt over was a breeze to use..what a treat to be able to complete an antenna tweak in about 2 minutes total time. Rig is ICOM 746 PRO and I am working all the DX I can hear.

'Protected' is the word. What is not always appreciated is that the
primary purpose of lightning rods (usually called 'lightning conductors'
in the UK) is to PREVENT a strike by allowing the electrical charge to
leak away before sufficient voltage builds up to cause an actual strike.

Me neither! The main lesson is that we have to be careful to define what we mean, because there's a strong risk that other people might understand something different.

Faraday cages are used at CERN and other large particle accelerators, to keep the sensitive particle detectors isolated from the pulsed megawatts of RF energy that are kicking the particles around the ring. CERN is an international facility, so each country has its own experiments using separate Faraday cages.

Several years ago, I needed to call a friend who was working at CERN. Someone picked up the phone, and a voice said "British Cage".

"Well," I thought, "that certainly puts us in our place..."

Could you not create low loss "coax" by using concentric pipes?
Might be easier than all this hacking around..

That, or run heliax in the buried section, and convert to balanced in a
little box on the other end.

# 4316. AM/FM outside antenna

Source record: 84613

Howdy: First off let me state that I am a complete idiot when it comes to antenna's. This will probably become painfully obvious after reading the rest of my post!

I have a bookshelf stereo system that has a rinky-dink little loop antenna for AM and a single little wire for FM, both of which run into a funny little plug that goes into the back of the set. No screws or ports to attach another antenna.

I live in a mobile home and it has a steel roof built over the top of it and I get no reception at all inside the house. In my car I can pick up AM/FM stations from Del Rio (30 miles away) and Uvalde (40 miles away) and even sometimes San Antonio, TX (120 miles away), but in the house, zilch!

I read somewhere that I could buy a shortwave antenna kit from Radio Shack and sting up the 100' feet of wire and that would be a good antenna for the radio. Did that and still no joy! The antenna is run from a tree to the edge of my steel roof and then along the edges of the joists. I then have an insulated wire soldered to this and run down the wall and through a window to the set. The whole thing does not touch metal anywhere, all stand-offs and insulators are used where required.

I've attached the stripped end of the lead-in wire to each of the leads from the back of the set individually and together in combinations, and still no joy. Just static. I've run the dial through the entire frequency bands and nothing. I've checked the whole antenna for anywhere it might come in contact with metal and made sure it was all insulated. It's about 15 feet off the ground and there are no high voltage wires, or wires of any kind anywhere around.

So with out berating me too severely around the head and shoulders, could some one tell me what I've done wrong and how to correct it?

Thanks for any help!

Nice to find such an interesting post on RRAA. And yes, George does have a nice sound.

It's interesting to me that many CW ops declare that their own callsign, however mundane, has an especially distinctive and appealing rhythm in Morse. Mine does too ... BDU, send the B, drop a dit, then turn it backwards. Logical like the laws of nature.

But NICK is another thing. You need an extra bit of pause between the N and the I for clarity. And a mis-heard extra dit at the start of the N makes me Rick, while one heard at the end changes me to Dick. Hmmm ...

I don't know history, but I do enjoy well written stories and opinions. Readers should go to Reg's page to see some more.

You should be able to take the unit outside and see if it can hear the stations on its own just outside the trailer. Maybe it can. Maybe it can't. If it is totally dead outside .. then is it defective? Then try the next step. Find a really weak station. Try attaching your new antenna to it in the same way you are attaching it to it while inside and see if the really weak station becomes more receiveable. You may find it does - or does not. If it does not, then the question you next need to answer is why not?

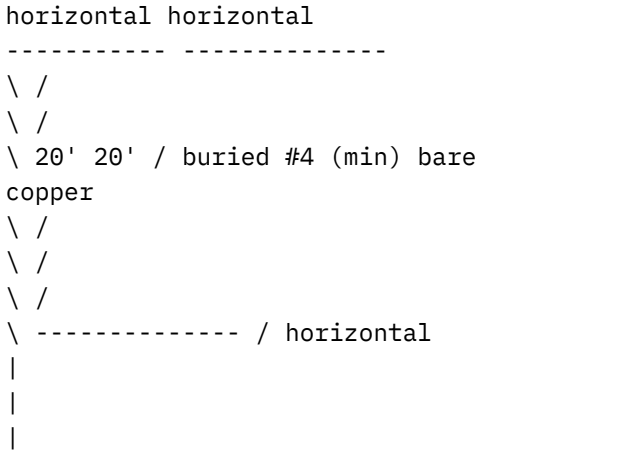
Hi Bob, the horizontal burying of ground rod is fine, although a minimum depth of 3' is recommended in NFPA-780. Follow the same plan as for vertical ground rods by burying two additional (min.#4 wire) conductors for another 20' in a "Y" direction and repeating a horizontal rod at each of those locations.



Even in dry soil this will be a much more effective ground than a single 8' vertical ground rod.

73,
Jack

Hi Gary, the study is of course much more detailed than the articles describe, I'll see if I can find you a link or post the abstract here anyway. But no, there is absolutely no such conclusion in that study (or any other accepted work) that any device can prevent lightning from striking a particular point by "draining off" charges.

Seabat wrote:
"I have a bookshelf stereo system that has a rinky-dink little loop antenna for AM and a single little wire for FM."

The designer likely assumed the loop and the wire would be immersed in AM and FM fields adequate for satisfactory reception.

The AM loop may not have enough signal because you`ve put it under a metal roof. The FM wire may not have enough signal because its elevation is too low at your site. You`re down in the Rio Grande valley.

The FM wire is likely about 2.5 feet long, or about 1/4-wavelength. Its impedance would be about 30 ohms near resonance.

The loop is likely part of the AM tuned input circuit with an impedance of about 1000 ohms.

For FM, you need to get the antenna up high. A ground-plane antenna is simple and works well. Vertical and radial parts can all be about 2.5 ft. long. It can be connected to your radio with 50-ohm coax. The existing wire is your FM input. Ground to the radio is probably one of the "rinky-dinky loop" wires. If not, capacitive coupling via aluminum foil or the like will likely do.

For AM, a tuned loop out from under the metal roof should capture ample signal. It can be enclosed in a non-metalic protection and does not need to be placed up high to work well. Wind a separate 2-turn coil around the loop to take out its signal. Connect this to yet another loop (which does not need to be tuned) via twisted pair. Place the untuned loop in the position next to the "rinky-dinky loop" which gives the best reception. When changing AM stations, you will need to retune the external loop for best reception.

Best regards, Richard Harrison, KB5WZI

Hi Ian, while Franklin originally thought this was the case, he and others soon realized that safe handling of a lightning attachment was the function of his Franklin Rods, NOT avoidance of attachment. There has never been any proof that any device can prevent a strike from attaching to a particular point. The controversy surrounding the CTS (Charge Transfer System) and ESE (Early Streamer Emitters) exposes some of the dumbest junk science ever to hit the lightning-rod snake-oil trail. It has been thoroughly discredited as having absolutely zero effectiveness as a preventer and limited usefulness as a standard Franklin Rod when installed as its snake-oil purveyors proscribe. So please never assume that any rod, termination device, voodoo-doll on the roof or anything else can have any affect whatsoever of preventing a strike from attaching at any particular point.

Message-ID: <fJAAd.7651$Y8.1656@newssvr17.news.prodigy.com>
Source record: 84526

Bob,
The 'quick'n'dirty' answer is don't waste your time burying
the ladder line. If you have to bury a feed line make it coax
(one of the reasons it was invented, to be able to run it close
to 'stuff', or ground). Still want to try it? Then why not. The
losses may be acceptible to you (sort of doubt that, but...), and
it would be an interesting experiment.
'Doc

ALTERNATIVE #1
Take up metal welding 'scupture'. Build a huge ~ugly~ thingy
in the backyard. Hang dipole over the top of it (call it a lightning
protection device). 'They' will be so upset over the 'sculpture'
they'll never even see the dipole. Invest in a good divorce attorney.

## 4330. Re: Good copper cleaner?

Source record: 84527

Bob,
An easy fix? Forget it. Pull the thing out of the
ground and replace it with hard drawn copper pipe.
'Water drill' it into the ground (keep large hammer handy
for the rocks). Better yet, lay out several hundred
radials (sure easy to tell others to do that, isn't it?).
An 'easy way' and a 'good way' are seldom the same thing.
'Doc

PS - Don't bother pulling the old ground rod out. Just
sink the new one near it.

A ham I know uses parallel runs of buried RG62 as a compromise.
That gives him a characteristic impedance of 186 ohms for his 30
foot underground section. It was interesting to model that setup
using MicroSmith.

Yes. It`s balanced to ground and has twice the characteristic impedance of a single run of coax. In the case of twin runs of RG 82, that is twice a value of 93 ohms, or 186 ohms, center conductor to center conductor.

I recall analog microwave radios which had their baseband signals wired with twin runs for each direction of transmission like that to obtain a shielded and balanced baseband system. It must have been good for the coax business and it made for a quiet radio too.

Best regards, Richard Harrison, KB5WZI

>
> I tried hooking the base unit antenna to the center wire of coax that
> goes to our rooftop TV antenna but that didn't work.

It turns out that particular coax feed from the TV antenna is broken or
something. The antenna line was put in by the prior owner and I just
assumed it worked. Later, I tested by hooking directly to an old TV
and found it does NOT work.

Another room in the house has a working TV antenna connection, and this
is the one I'm now using.

Here's the steps I took.

1) Opened the receiver case and removed the original antenna.
2) Reamed a round hole in the case to take a solder lug coax terminal.
3) Installed the coax terminal: Soldered the antenna wire to the
solder lug for the center coax conductor. Soldered one end of a 20
gauge wire to the ground plane of the recevier. Wrapped the other end
around the shell of the coax terminal. (They probably make coax
terminals with two lugs but that was
not in my parts bin.) Tightened a coax nut around the wrapped portion.
4) Closed the case. Tested.

I found out from the FCC web site that the transmitter uses 315MHz, so
that's within the range of frequencies TV antennas must grab. We're
out in the mountains. Our TV antenna looks very directional, so I made
sure to point it at the mailbox to maximize reception. We are using
satelite TV now, so at least we can use the old antenna for something.

It works, but I've yet to see how dependable this is. Will post again
if warranted. I have an old Radio Shack UHF/VHF/FM amplifier kicking
around and
could always put it on in case the signal is still too weak.

# 4342. Old Wives' Tales & Ground Rods

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-29 22:55:49 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cqvcll$md2$1@sparta.btinternet.com>
Source record: 84539

There are so many Old Wives' tales about ground rods that I feel impelled to correct some errors by re-stating a few elementary facts from my notebooks.

I am at present quite sober, not having imbibed for two days. I do, of course, take the prescribed hyper-tension pills.

The following applies to rods used for both lightning protection and for radio grounding purposes. It is assumed that rod length, or depth, is very, very short in terms of RF wavelength. It can even be forgotten the RF propagation velocity along conductors buried in the ground can be very much slower than the free-space velocity.

We are concerned, very simply, with the resistance in R ohms of the connection between a tiny electrode and the great mass of Mother Earth.

To gain an idea of the magnitudes involved it can be stated that the most simple electrode is of hemispherical shape impressed into the soil surface, which has a resistance of exactly -

R = S / Pi / D ohms, where -

S = Soil resistivity in ohm-metres, and -

D = Diameter of the hemispherical electrode in metres.

Soil resistivity is the resistance measured in ohms between two opposite faces of a 1-metre cube of the material. Which is the more practical reciprocal of the too-often used scientific measurement unit of conductivity. Conductivity sounds good!

Thus, a small hemisphere, 1-metre in diameter, impressed in the soil to its radial depth, with a typical soil resistivity of 100 ohm-metres, will have a moderately low resistance of 32 ohms. Now, like Kelvin, we can see what we are talking about.

Getting down to brass tacks - the resistance R of a ground rod, D metres in diameter, of length L metres, provided L > 5 * D, is approximately -

R = S / 2 / L * Ln( 4 * L / D ) ohms.

An approximation is good enough because nobody knows the value of their local ground resistivity anyway.

It will be noticed from the foregoing equation the resistance is almost entirely due to rod length and little to do with its diameter. So much for Old Wives' clever calculations about the surface area of rods in contact with the soil.

Practically the whole of the resistance is due to that thin layer of soil in contact with the rod and in its immediate vicinity. The soil beyond a distance equal to twice the depth of the rod has little effect on resistance R. At a distance the cross-sectional area of the current flowing through it is too large. The electrode, whatever its shape, behaves just as if it were a hemisphere with a radius roughly equal to its length.

Incidentally, the volts at the soil surface at a short distance from any electrode of any shape, due to a lightning stroke, can be calculated by asuming a hemispherical electrode. The current flowing away from the stroke always being in radial directions. The same applies to RF currents from a ground rod or the approximate centre of a collection of ground rods.

From similar similar reasoning, there is not much point in spacing ground rods much closer together than a distance equal to twice their depth for either lightning or RF grounding purposes.

Corrosion of copper sheathed or plated ground rods -

Because thin corrosion products have a far lower resistance than the soil in the immediate vicinity of a rod, and it is soil resistance in the immediate vicinity which predominates, the rod resistance whatever its material, steel or carbon even, can always be considered to be zero. It is always smaller than any other contributions to ground resistance except for the ignored rod resistance itself. So the foregoing simple equations still apply.

So although it may make you feel better, it is wasted effort to extract a ground rod merely to brighten up its appearance. Just allow a 1" diameter rod to rust away for years and years. The diameter was needed only to drive it into the ground. Its the electrical connection as viewed from the top which matters.

Having consumed 3/4 bottle of Californian, red, Blossom Hill, I am not quite so sober as I was when I first began this technical dissertation.

I hear in the news that more than 100,000 people have lost their lives and many more will die in the wake of the recent earthquake. Recent very similar figures of casualties incurred from continued USA use of weapons of mass-destruction in Iraq and Afganistan have hardly been mentioned. Military and political press censorship?

I wish all USA citizens and voters a very happy, prosperous and peaceful 2005. After all, you have the means of enforcing it!

I'd say it's more a case of people tending to think that various metal structures such as cars, airplnes, metal boxes, etc. are close to ideal 'Faraday shields' when, in actuality, they might only be a poor approximation. (It's this line of reasoning that usually flummuxes people when they try to shield a monitor that has a wavvy display from some extneral field with a steel box and find it's not very effective.)

> I have seen radars inside quonset huts track a *bird* flying a few
> miles away (thru the metal wall)!

Hmm... any idea if the folks inside weren't being exposed to far more radiation that what we'd typically consider safe? :-)

The ONLY way you can obtain a horizontal, omni-directional, dipole antenna
is by using a "turnstile" with a 90-degree phase difference between the pair
of crossed dipoles.

You get a 3dB loss relative to a simple dipole, uniform in all directions.

Is this what you really want?

There's a Simpsons episode where Homer and Marge check out the house for
sale next door, and find that it has a very high end, contemporary kitchen
including a microwave oven big enough to walk in... something that Homer
immediately does, of course.

How about an S-curve folded dipole, or a classic "Big Wheel" with
three roughly-full-wavelength piece-of-pie elements fed in parallel?

I can send you an AO (miniNEC) model of a triangular antenna that has a
better omni pattern than a turnstile- or better yet, go to W4RNL's site and
do a search under triangular omnis.

BTW, to the oriiginal poster:
a full wavelength loop does NOT have an omni pattern- its pattern is very
similar to a half wave dipole.

My favourite technological American Hero is a name which I cannot remember at present and I seldom have much success with Google.

It was in the age of early chemical engineering and the manufacture of sulphuric acid. Sulphuric acid was, in the Victorian age, and still is, the foundation of chemical engineering. From the age of steam the progress of an industrial country could not advance without great quantities of sulphuric acid which was usable in the production of a vast range of other chemicals from fertilisers, explosives, medicines, battery acids, dyes and eventually micro-processor chips.

The person concerned was the usual ragged-trousers European who arrived penniless at the shores of America before they took fingerprints. He had some rudimentary chemical engineering experience obtained probably in France or Germany where sulphuric acid was already being manufactured in small quantities.

Manufacture was in small vats made with very pure thick lead. Lead is a metal relatively impervious to attack from sulphuric acid. But pure lead was a very expensive metal in those days. It probably still is.

To reduce the exorbitant manufacturing costs of sulphuric acid the person had the brilliant idea of using ridiculously cheap timber vats painted with ridiculously cheap coal tar. The whole USA chemical industry immediately boomed, eventually overtaking Germany, and expanded into all fields making the USA what it is at present - far and away the World's greatest and richest industrial nation.

All based on dirt-cheap timber and coal tar. What a pity USA presidents still have their brains lined with heavy lead, unable to walk and chew gum at the same time.

Praps someone will remind me of the person's name.

Interesting to know Lea & Perrins Worcester Sauce is available in the USA.

I live in the next county to Worcestershire.

I cook for myself and use a small bottle in two or three weeks.

But as for your subsidiary use on ground rods I hope they're made of carbon.
Ordinary metals are less resistant to attack than my stomach lining.

The other devices may have circuits that incidentally radiate a little noise
in the aircraft VHF band.
A broadcast FM receiver almost certainly has an oscillator running by
design, in the band.
Where it lands in the aircraft band, is determined by where it's tuned to.

Hi Reggie,

Back in the 60s, a black comic by the name of Godfrey Cambridge used
the name as the punch line to a joke about one of his forbears (an
uncle perhaps) who was visiting in England. It seems he was served a
dish with that garnish and it was named upon his exclamation:
"Wus dis here sauce?"

Richard, I can only admire your adeptness at judging my motives for the intervention.

But you are not exactly correct. Let's await further developments - if any!

( I really do think the English and USA written languages are coming close together again. Welcome! All due to that modern invention - the Internet.)

( I understand the BBC Over-seas Service is widely heard in the USA - again over the Internet rather than the old-fashioned, beamed, short-wave radio waves.)

"Wasn`t Franklin that lunatic who used to walk around hlying kites in thunderstorms?"

Story is that Ben Franklin (see $100 bill for portrait) was looking around his house searching for a metal key to use as an attraction for lightning. (My neighbor says his kids have lost so many tools that his back yard is struck repeatedly in thunderstorms.) Ben thought he had mislaid a new key somewhere. When Ben asked his wife for it she told him to "go fly a kite". So Franklin showed that charge in a cloud was the same in nature as chsrge in a jar (an early capacitor).

Best regards, Richard Harrison, KB5WZI

Finally, success at last!!

I tried the Lea & Perrins Worchestershire overnight on the corroded
ground rod. It did little but attract 2-inch cockroaches.

This morning, I brought out the heavy stuff: a mixture of vinegar,
lemon juice and salt, applied with a steel wool pad.

It still wasn't working; my VOM showed no continuity.

So, a trip to Lowes for Brasso and sandpaper.

The Brasso did nothing. But the sandpaper (#150 fine) seemed to do the
trick. Now my VOM shows continuity in the cleaned area of the rod.

I'll probably augment this old ground rod with a new one laid in a
horizontal ditch (got rock about 12" down), but at least the old rod
is working again.

It would seem increasingly the case in Britland that the
only good clean copper is a dead one.

Blakelock and the like are public justice in reparation for the
number of people killed by the plods; plods who then get off
scot-free.

================================

Jack, I enjoyed the whole site. Thanks for your introduction.

So the production of sulphuric acid began in the USA around the time of the French Revolution and the guillotine. The very first enterprising production engineer, John Harrison, who must have been aware of the most serious, Earth-shaking, consequences of events in Paris, clearly had other more useful, less destructive yet beneficial, things to think about.

I just love linking unrelated facts together.

But Harrison is not the name of the person on my mind who transformed the USA chemical industry to one based on sulphuric acid, timber planks and coal tar. I am under the impression he was of a later generation. Out of the canal and barge-horse age and into the age of Watt's condensing steam engine.

But what's in a name anyway?

I sometimes think that the relatively few engineers between 1790 and 1890 performed greater engineering feats than the many who followed them into the present age of electronic and genetic engineering. They devoted the whole of their lives to their work.

As for us poor souls, the best we can manage is haggling about imaginary SWR and conjugate matches which were all sorted out 120 years back. But it's all good fun.

Cheers, Reg.

Hamstick dipoles work pretty well for 20m-10m. Not well for 40m
and terrible for 75m (unless the application is a special one
like the portable NVIS application in the latest QST).

Hi Reggie,

I can see why you would have such trouble with Google in this regard.
The words tar and sulphuric acid would lead to a jillion pages about
creosote production and the words wood and sulphuric acid would lead
to a mega-jillion pages about paper production. I spent a lot of time
spilling H2SO4 on me while measuring the K and Kappa of paper.

Anyway, it seems that lead kiln towers (upwards to 5 stories tall)
were used in acid production well into the mid century:
http://www.ul.ie/~childsp/CinA/Issue61/TOC20_ChemClassics.html

Some odd facts:
In 1746, John Roebuck established the lead chamber process,

In 1831, the modern Contact Process was patented by Peregrine
Phillips, a British vinegar merchant

Reg, this may come as a surprise to you, but most Americans do NOT
appreciate vicious and absurd leftist slanders directed at our country.
(This is true even though some of our own citizens engage in similar
antics.) So I have to reject your New Year's wishes, pleasant though
they are. You might do well to respect your body a bit more vis-a-vis
what you ingest. There seems to be something hallucinatory in the mix.
BTW, who do you plan to call when the terrorists put the UK in their
crosshairs... the French?

This may also surprise you: Unlike WWII (in both of our countries),
our media is almost completely free to give aid and comfort to our
enemies via anti-US reports and propaganda; and since the Left is over-
represented in said media, they rarely miss an opportunity to do so.

But to close on a more positive note, many Americans greatly appreciate
Tony Blair's very courageous support. I do, and I will keep it in mind
when deciding which side of the channel to spend tourist $.

"My favorite technological American Hero is a name which I cannot remember at present and I seldom have much success with Google."

The very successful American producer of sulphuric acid shares a name made famous by an English carpenter who won the prize offered for the first chronometer or orher means accurate enough to determine one`s position at sea. John Harrison was that carpenter. His inspired and determined work is honored at the British National Maritime Museum at Greenwich. The scientific community would not believe that the carpenter clod had succeeded, Besides, the instrument didn`t look like a chronometer. Ir looked more like a pocket watch. So, Harrison was only able to collect his entire prize after an audience with the king who agreed he had won. The hing declared: "By God, you shall have your prize!"

Hi all,
I received e-mail this evening telling me that it is nice to have Harry's Homebrew Homepages back again!! They never went anywhere. I know that the number of visitors has declined, but I am still very much alive and kicking.

The URL is http://web.telia.com/~u85920178/

I had assumed that http://web.telia.com/~u85920178/ was so difficult to remember that a few visitors had forgotten me, but over last year I have got a new messageboard at http://amazingforums.com/forum2/SM0VPO/forum.html and introduced a couple of new projects, including a 400mW 88-108MHz PA (works well at 50MHz, 70MHz and 144MHz), and a VHF gain antenna, with calculator, that can be built and tested within about 15 minutes (50MHz to 900MHz - works well on 144-432MHz and 446MHz).

My e-mail address sm0vpo(at)home(dot)se got100's of messages each time I logged on: 95% SPAM. I filled the mailbox and deleted the account from Outlook. After a year of messages bouncing I hope the spammers will have moved on and I can use it again. In the meantime you can write to me on oeieio(at)hotmail.com or the old trusty harryvpo(at)hotmail.com (if the SPAM there continues I may close harryvpo).

New projects for the new year? Yes. Loads of ideas, some already in progress, including:
- Article about static electricity - will include a bit of humour
- Stereo encoder
- Tuneable VHF NBFM Receiver for 145-156MHz
(or any 1MHz chunk from 50MHz to 500MHz)
- Tuneable VHF NBFM transmitter (---ditto---)
- Practical antenna info - how-to, with photo's
- Soldering video (15 minutes VCD) still on the list

BR Harry

# 4384. Antenna building questions

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-31 01:19:44 UTC

Message-ID: <1104455984.838298.225650@z14g2000cwz.googlegroups.com>
Source record: 84481

I am interested i building my own antennas like to start with a 2meter dipole.
My questions is, say you have a plan that says to use 1/2 inch copper. How do you know what will happen if you use thicker material like 3/4 inch tubing? Is there a formula that shows what the effect will be? Or maybe efen smaller diameter? Or what if you use solid material instead of hollow tubing.

What if you use the same diamter but a different material, such as stainless steel instead of copper or aluminum instead of copper? Please forgive these questions if they seem basic as I am a beginner. My guess is the thickness of the element is not as important as the spacing between elements but this only can be true to a point. I mean for arguments sake what if you used large sewer pipe? I would guess that would not work too well.

Yes there is a formula. Generally speaking the larger the diameter in respect to the length, the shorter the antenna is overall. I dont believe there is any difference between solid core and air core when it comes to calculating the length. Types of material do have an effect but in my experience you can ignore it.

The length is also affected by other nearby objects and ground. Your feeding system (where the coax connects) can also affect it. Two halfwaves in phase for example will tend to be shorter than one by itself.

You can also make a slot antenna. This is a sheet of metal with a rectangular piece cut out and the feed at the middle at each side. From memory these antennas need to have about 10% longer length than a halfwave. A sewer pipe will also work fine.

You can certainly look up the formula on Google etc.

If you are building a simple dipole its not going to be too critical anyway. For the diameters you specified I'd subtract maybe 1/8" as a starting point.

Try experimenting!

Cheers Bob VK2YQA

Jack Painter wrote:
"Scientists have now shown that blunt-tipped air terminals are attached by lightning significantly higher frequency than sharp rods are."

I would have expected that sharp-pointed rods would be struck more often.

My CRC "Handbook of Chemistry and Physics" starts its coverage of "Electricity and Magneyism with a page on Spark Gap Voltages. In every case for a given breakdown voltage, the gap must be substantially wider when the electrodes are needle-points than when they are spheres. For example: With a voltage across the electrodes of 5 KV, the gap space between needle-points needed to prevent a spark is 0.42 cm. The gap between 5-cm sphheres is 0.15 cm under the same conditions. Much closer before sparking points obviously means sharp points engourage breakdown of the air between the points, while spherical (blunt) spark-gap electrodes discourage the spark.

It`s been said that if the chsrges dont pile op at the pointed end of a conductor, it would not have an equipotential surface as is required by the conductivity ("College Physics" by Franklin Miller, Jr.

b) ground connected to the rf gnd terminal

# 4392. Antenna impedance analyzer comparison

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-31 03:46:45 UTC
From: tf3kx@simnet.is
Message-ID: <cc4f4620.0412301946.274e77dc@posting.google.com>
Source record: 84489

Hi - I am looking for an impedance analyzer. Primarily for antenna measurements (only 1,8-30 MHz) and secondarily for misc. lab measurements (L,C,Q measurements, signal generation, etc.). The possibilities I have been looking at are (in no particular order, prices approximate):

a) MFJ-259B ($300)
b) MFJ-269 ($220)
c) AEA VIA ($600)
d) Autek VA1 ($200)
d) Micro908 kit from AmQRP ($210)
e) N2PK Vector Network Analyzer project ($150)

At first glance I have the following points/questions:

- Does MFJ-269 offer anything over 259B in addition to VHF/UHF?
- W8WWV tests (web) don't indicate that AEA VIA performs better than the MFJs.
- Micro908 is new. Any experiences, comments on impedance accuracy?
- N2PK may be the most accurate(?) but needs a PC and involved construction.
- Any comments on the Autek?

All suggestions are appreciated, based on experience and technical quality.

# 4394. Decoupling coax transmission line

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-31 05:35:36 UTC
From: Charlie <charlie@earthlink.com>
Message-ID: <10t9p9h2iou90fa@news.supernews.com>
Source record: 84491

I have 50ft of 9914f feeding a ground mounted 4-BTV. After a little tweaking I have advertised swr across the 4 bands. (1.6:1 or less). The 4-BTV instructions recommend a coaxial choke for "de-coupling the transmission line".

I would like to be able to do some kind of analysis to see if I really need to do this or not. Also with buried coax if I did so would the coax choke get buried too? They (Hustler) recommend 10 turns of coax on a 6 inch form. I am really pleased with the station so far ( about a week old!) and cannot see any symptoms that I need this choke. I have a 6ft ground rod about 2 ft from the rig and all is well best I can tell. What would some of the symptoms be if I needed this rf choke?

Hi Richard, yes, you and Ben Franklin agreed on that. Modeling examples you cited below appear to be incorrect for lightning, similar to how modeling for ocean waves cannot be done in a bathtub, and even a swimming pool does not closely replicate the action of waves in a large body of water. The experiments and the conclusions offered by the blunt-tip lightning rod tests were peer reviewed, are repeatable, and are being further studied. Their conclusions describe behavior that was not expected or explainable by current modeling. However it is easy to rocket-trigger lightning and this is being done on a daily basis, so a few thousand repeatable findings should soon arrive at a more permanent conclusion. Whether or not that is explainable in terms that classroom scientists can model remains to be seen. An awful lot of engineers have accepted the findings already, and specify blunt-tip rods on new construction. The same cannot be said about other questionable and unrepeatable theory such as charge transfer systems and lightning charge dissipators. Their popularity relies soley on the ability of snake-oil salesman conning a confused public.

If the coax is buried, you should not need any further decoupling. Any RF current on the outside of the coax should end up amost entirely on the ground.

I once had a 4BTV roof-mounted and didn't have many radials on it. I didn't need decoupling for most bands, but 10 meters was downright awful with high RF at the transmitter. I solved it by winding a few turns of the coax to get a choke that was self-resonant at 10 meters...I seem to recall that I might have actually put a little extra capacitance across the coil to tune it, but it was a long time ago.

If you put a neon light next to your coax near the transmitter and it lights up when the transmitter is sending power to the antenna, it's an indication you have lots of RF on the outside of your coax, and decoupling is in order. You can do the same thing with greater sensitivity using a small coil feeding a field strength meter...high fields near the coax indicate current on the outside of the coax.
Cheers,
Tom

Thanks Tom that was a great reply. I was totally unaware that burying the coax had that extra benefit. Adding the 75 meter resonator tomorrow and will see how that affects things. Even without the resonator I hear DX stations on 75M at night..

I do have quite few tuned radials with 20 on 10,15, and 20M respectively and 12 on 40m. I really do not room for any 75M radials. Hope I won't need them. With over 50 inches of rain a year and the other 72 radials maybe I won't...

# 4398. Re: best low dipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-31 08:23:26 UTC
From: Rick Frazier <rickf@rickfrazier.com>
Message-ID: <41D50CB4.C57E7836@rickfrazier.com>
Source record: 84495

If you can only get the antenna up 10 feet, forget about the carolina windom. It relies on the vertical section, and unless you can get the antenna high enough so the vertical section is above ground, the antenna is miserable to live with. Even when the vertical section is all vertical (the isolator at the bottom of the vertical section is near the ground) the antenna doesn't perform as I think it should. I have a 160 carolina windom, and with the short end at 40 feet, the long end needs to be at least ten feet off of the ground before the antenna starts to work well. If the long end is lower than that, the isolator at the bottom of the vertical section nearly touches the ground, and swr gets worse and the low swr points move out of the ham bands...

I've found that some monofilament fishing line and a few sinkers can be invaluable for getting a temporary antenna up higher than I can reach... There are usually some sort of objects (trees, buildings, poles, etc) that can be used to get an antenna up a bit if you are using monofilament to hoist the ends up. I've got away with all sorts of temporary antennas in some pretty unlikely places, using little more than some fishing line and 24 gauge insulated wire. 30 gauge would be even better, as it's nearly invisible, but it tends to be too fragile for my hoisting techniques... Your mileage may vary...

Thanks

there will probably be some impedance mismatch but in most cases the extra loss will probably be minimal. worse than that are the mechanical and weather proofing problems. they are much worse on rca than either bnc or uhf connectors. i would also worry about high power rf through them. if they are only for short term use and in a weatherproof enclosure and being used for low power or just rx then there shouldn't be a problem.

Using 174 coax you do not have to worry about the power ratings of the connectors. Some of the GE rigs used the RCA connectors at levels of 100 watts . The older Heathkit low band rigs used them on their 100 watt rigs.

Mismatch between what and what? Neither the UHF or RCA or constant Z
connectors to begin with. The antenna is likely not 50 Ohms, at least across
any bandwidth, the rig is probably not 50 Ohms.

Actually, for MOST applications, the polarity will make no difference.
The ONLY eception would be if you were stacking 2, or more antennas
(like , say 2 tribanders in phase, which in itself would be an awesome
sight!). Just hook it up and work the world!

That was back in the days when fantastic claims were settled with a working model. If you wanted to argue about the efficiency of a venturi, or the strength of a gear tooth profile, you built it and then actually used it. If your drill bit stayed sharp longer, or you pumped more water with less coal, you won your argument.

We spend a lot of time now arguing about how well the computer model replicates reality, and whether the math has enough variables accounted for. Working models seem so old fashioned.

No problem at all: At 174 kcs. you'll never notice the difference.

Ken, KC2JDY wrote:
"---RCA connectors, will there be a material difference in insertion loss?"

The RCA pin size is large enough for low resistance contact, and insulation quality can be good enough for low leakage. RCA connectors were routinely used in Motorola 2-way radios to make connection to its internal receiver 455 KHz intermediate frequency filter. This says nothing about possible loss but does indicate suitabikity for some RF applications.

Outside world RF connection to Mottorola 2-way radios was usually via the familiar "UHF" (SO-239). These stay connected when yanked and are simple and easy to connect to the coax. A bonus is that the center-conductor pin socked is designed to accept a banana plug.

All common coax connectors are usually too short to represent much of an impedance bunp.

Best regards, Richard Harrison, KB5WZI

"If the plan calls for 1/2 inch and I go with a larger diameter, say one inch, would the spacing between the elements still be the same?"

Maybe not, if impedance of the line segment is important. See a chart like Fig 19 on page 24-15 of the 19th edition of the "ARRL Antenna Book". This shows "Characteristic impedance as a function of conductor spacing and size for parallel conductor lines."

Best regards, Richard Harrison, KB5WZI

Charlie, an antenna will need to have a choke only in the following condition:
Check the Swr with feedline attached. Add another 1/4 wavelength of transmission line with impdedance equal to the output of your transmitter. If the Swr increases, then a choke is required. If Swr goes down slightly, that only means that there is loss in the added section of feedline.
The reason why this check works is that a choke is needed if current exists on the outside of the coax. In that case, the current acts like another wire attached to the antenna. This added wire changes the effective length of the antenna causing a change in resonance with added feedline.

I have the Autek RF1 and enjoy it a lot. My only comment is that
battery consumption is probably more of an issue than people realize.
I feel sorry for those with an analyser that uses a lot of batteries.
My Autek is small and power consumption is low, but even then,
replacing the single 9v battery is a pain because it always fails when
I'm somewhere up in the air!.

OK. Here are full-scale examples. My company had radio towers over much of the earth. Standard practice was protection of the beacon atop the tower with a Copperweld ground rod alongside the beacon with its sharp tip pointed at the sky. No protected beacon was ever damaged by lightning.

Our company headquarters skyscraper was protected by short air terminals ringing the perophery of the builsing at short regular intervals. No lightning damage yet in half a century.

You may say it is squivalent to the fellow who walks into a bar with a strange contrivance suspended around his neck. Asked what the gadgst does, the new arrival says: "it`s an elephant whistle". Reply is: "There`s no elephants around here." New arrival says: "See. It works, doesn`t it?"

I can assure that there have been plenty of lightning strikes safely bypassed to ground around the protected people and equipment, just as Ben Franklin and others have predicted.

The RCA connector has been demonstrated to show a flat response from DC to Light. The only problem with this connector is that it is hard solder coax to the blasted thing.

I've used an Autek VA1 for a few years. Carried it on a
sailboat to the Bahamas (in a plastic sack). No problems
with it at all. I unplug the battery when it is not in use.
The VA1 is a very useful piece of equipment.

My opinion of Autek construction and documentation, however,
is that it makes MFJ look good.

> tuner & work 20-10 mtrs.?

The problem with using hamsticks on higher frequencies is the loss in the coil. The 20m hamstick has too much inductance for any higher frequency and thus has more loss. Losses are probably worst case at the self-resonant frequency but I don't know what that frequency is for a 20m hamstick and I don't have a 20m hamstick to test. Perhaps someone with a 20m hamstick and an MFJ-259 will run that test and report the results. In general, though, it is not a good idea to use hamsticks on higher frequencies than their resonant frequencies.

However, using parallel 18 MHz hamsticks with ladder-line to cover 20m, 17m, and 15m is probably not a terrible idea.

Lakeview sells a dipole mount for use with its Hamsticks. It would
seem you could put the thing up, attach your coax feedline, and then
just change out Hamsticks for the appropos bands.

Hi Richard, because it is completely unlike you to so widely miss the point, I question whether I understood your responses correctly. The standard Franklin rods (with pointed tips) have been completely validated in their application of safely terminating lightning strikes. Nothing in the new study repudiates that in any way. It simply finds that a lightning rod of similar length, thickness and composition but with a rounded or blunt-tip, has attached lightning that was coming to it's twenty-odd foot area everytime and missed the nearby Franklin rods everytime. The study clearly restates what engineers all over the world already know, that Franklin rods work just fine. But it ADDS that the blunt-tip rods work better, end of study.

Because lightning is impossible to predict, and often it strikes areas of a grounding system and building below the lightning rods (evidence is the Empire State Bldg, which has video showing dozens of strikes bypassing the

Franklin rods), then if an improved rod-tip design is validated, then it is validated, simple as that. Your experience describing a pointed tip protecting a radio tower sounds rather simplistic as examples, don't you agree? Nothing could be easier than attaching lightning to the top of a tower for Pete's sake. Where lightning rod placement and design becomes critical, is in areas such as multi-level/shaped building corners, appurtenances, high explosive and flammable liquid storage, etc. Here, the best available science is used to describe how many feet apart, at what elevations, etc the air terminal system must be in order to achieve the desired level of confidence that no lightning attachment will cause damage to structures, materials or personnel.

Happy New Year and best wishes,

Jack Painter

>
=====================================

It is a fatal mistake to treat a modelling program, even if you think it has no bugs (errors), as a bible which always tells the gospel truth. ALL programs have limitations.

Limitations result from the computer itself, those deliberately introduced by the programmer, those accidentally introduced by the programmer because he didn't understand how the thing being modelled really works, those introduced by the user because he doesn't understand how the program is supposed to work or what the programmer was thinking about when he wrote it.

The result is UNRELIABILITY.

Ideally, the originator of the thing being modelled and the programmer should be one and the same person. Committies produce drumadaries with 3 or more humps. Or elephants with trunks at both ends.

The definition of Reliability is Quality versus Time, and therefore confidence (or lack of it) can be gained only with both use and time.

Given time, and use, with large programs, such statistics as mean-time-between-failures can be produced. But when the next error might arise and its magnitude is anybody's guess. One is always caught unawares. More insidiously, one may not be aware that an error HAS occurred. Or most insidiously, one may imagine an error has occurred when it hasn't.

Problems will surely persist - if a failure is suspected, is it the program which has failed, is it the computer, is it the modelling, or is it the actual thing being modelled (it may not exist) which is defective?

The proof of the pudding lies in the eating. Get off your ass, wrench yourself away from the keyboard, do what you should have done in the first place, erect the thing and use an instrument which purports to measure SWR, hope for the best, don't swear by it, and take care to record the instrument manufacturer's name and its serial number. ;o)

To summarise, the reliabilty of a modelling program is always worse than the quality of the blamed programmer. Initially, don't believe anything it produces.

And whatever you do, don't become depressed. Even if the program doesn't work the radio will. Most happy-band radio amateurs don't realise how fortunate they are - almost anything works thank goodness.

At present I'm on Spanish Red, Berberna, Reserva 2000. I know it's Spanish because, unusually, the entire blurb on the bottle is in that language. But I feel somewhat guilty because at the back of my mind there's the continuing unbelievable horror of the enormous disaster in the countries surrounding the Eastern Indian Ocean. The worst effects may still be to come.

Source record: 84431

Hi,

I was wondering if anyone out there has
designed a GSM and PCS (880MHz and
1910MHz) dual-band printed circuit board
embedded antenna? I expect the design
would include a parallel LC network, so
that the electrical length changes depending
on the injected frequency.

If you have done so, did you use Microwave office
or Momentum, or any other computer simulator?
Thanks in advance!

Slick

Maybe not a league of its own--for another VNA (not out yet, but
hopefully soon), see <http://www.tapr.org>.

I looked at this at Dayton- from memory, I seem to recall the dynamic range was nowhere close to Paul's design and software at that time was rather crude. I'll look again, but for the price, Paul's design is hard to beat-accuracy right up there with the Agilent 40 Gigabuck units.

Specify the operating frequency range. Up to 100 MHz, not a problem. At 10 GHz I'd worry about it.

I like the welding idea but sold my arc welder b4 moving to the new house
:-(
I've been playing with an end fed 100' wire antenna and it seems to work
pretty well and is nearly invisible to boot. I've got access to trees maybe
200, 300 feet out. Just need to pick up a wristrocket.

Fully functional, EXCEPT for making the default reply button not quote the
text of the previous post! If Google is used on a busy group it can get
very difficult to figure out what is actually being replied to. It gets
annoying to have to go and read other posts in the tree just to
figure the thread out.

Apparently there is a way of replying that quotes the previous text, but
this involves clicking on a few buttons to do it.

# 4442. 30 + J200, 25 - J350 etc Refresher Course ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-12-31 23:41:48 UTC
From: nospam@nospam.com
Message-ID: <d0obt09nl4o672ptfnnurjmvqm3te5tdg7@4ax.com>

I'm basically a lurker in the newsgroup but I've forgotten what the term as used with an antenna impedance like 30 +J200 or 25 -J150 etc means. I remember studying it about 10 years ago when I took my extra test and I had it in tech school at about the same time from a Jr. College during one 4 credit hour "communications" course that covered everything from TV's to SSB and FM. I believe it's one way of expressing an impedance with some reactance thrown in and I recall converting between polar and rectangular methods of expressing the same term ( I would really need the book for that now ! ) But I don't think I have the books from the school days around anymore. Any one care to give me a short refresher course or post a URL ? I've got a bad case of CRS ( Can't Remeber Stuff ;-) )

Happy New Year !
